Abstract

Containers: The Future of Virtualization & SDDC

This session will appeal to Data Center Managers, Development Managers, and those that are seeking a fundamental understanding of the future of virtualization and next generation software defined data centers both on-premise and in clouds. The session delves into the emergence of containers as the next generation of virtualization to run multiple applications without a hypervisor and as the light weight platform that will extend to software defined data centers (SDDC). Their rapid adoption by both startups and major IT vendors is a testament to their "Build and Configure once, run anywhere" portability between On-Premise DCs to Clouds., The session is targeted to bring a clear understanding of this key technology to developers as well as systems admins and cloud service providers

IT Industry Roadmap

Data Center IT Issues & Solutions

Issue	Industry Solution
• VMs/Hypervisor treated all apps as same	Workload I/O Optimized Infrastructure
✓ Created Blender Effect	• Solid State/Flash for I/O intensive Apps (e.g. OLTP)
✓ Poor Performance of some VMs	• Application segregated by Frequency of use into Hot/Warm/Cold Storage
• Each Application is different and depending on its	• Must identify various Metrics to meet SLA needs such as
SLA/mission criticality needs in the Data Center or	Availability, Performance, Cost, Security etc. (e.g. Performance
Cloud	metrics - Latency vs Bandwidth)
• Storage must meet 2 major criteria of	Implement technologies
✓ Data Protection	✓ RAID, Continuous Availability,
✓ Storage Efficiency	✓ Compression, Encryption,
• Real-Time IT/Databases needed for both	Implement New technologies
 On-line Transaction Processing to 	✓ RDBMS/Big Data/Virtualization VMs,
✓ Real-Time Deep Queries	✓ Columnar Compression
✓ Cloud Queries Exploding	✓ Use of Lightweight Containers with no Hypervisor or not
✓ VMs heavy due having to load 10-20 MB of OS	having to load OS – witness Google containers using 7000
from storage slowing queries	queries per second

• Virtualization: Impact on IT Infrastructure

Multiple VMs create I/O Blender

Virtualization led Workload Consolidation provided >20x Savings in RE, Pwr., HA

Container = Hottest Trend in Data Center Innovation

- Container = Opening next wave of optimization of computing power usage post VMs
- Container = Lightweight OS Level Virtualization
- Container = Runs Multiple Apps without a Hypervisor
- Container = Build and Configure Once , Run Anywhere
- Container = Key to Google Search Engine speeds Google - World's largest Linux Containers User Google Search launches 7000 containers/sec Search App in Container launches in msec

Containers: An open source app portability platform that packages app and its dependent component parts into a hardware isolated container Containers provide a more efficient use of Resources:: Eliminates Hypervisor reducing virtualization overhead while still allowing separation and isolation of multiple tasks on one host without relying on a separate OS, saving huge amount of HW resources compared to bulky VMs which emulate physical servers complete with OS **Allows Easy Application Portability** between different hosts within DCs, DC to DC/DC to Cloud (Private, Public, Hybrid) / Cloud to Cloud **Rapidly gaining adoption:** Over15000 aps have been "containerized" and available on Docker Hub repositories, ready for server admins and cloud server providers to deploy both as free and paid options. Significant buy-in from both start-ups and large vendors: : Repositories – Ubuntu, Redis, MySQL, mongo DB etc. OS Vendors - Red Hat, SUSE, CoreOS, Boot2Docker - Mac & Windows ... Clouds – IBM, Amazon, Microsoft, Rackspace, Google, Intel etc. Major Users - Paypal, eBay, Google, Spotify etc..

Containers: Pros & Cons

Pros

- Containers pack more computing workloads onto a single server
- Launch capacity for new computing jobs in a split second vs minutes for VMs since no loading of OS from storage required
- Appealing to Virtualization Admins and Cloud Providers to maximize consolidation and improve resources efficiency in multi-tenant price-sensitive environments
- Developers able to rapidly move their applications from concept to production since no need to boot up an OS instance of Linux or Windows for every app run
- Efficiency driven from speed allows improvements in CapEx (Buy less HW) or OpEx (Build/Rent less DC space, Fewer people in operations/maintenance).
- Speed lets DCs respond quickly in case of a sudden spike in business activity (explosion in searches/queries or Black Friday promotion driven sales orders)

Cons

- Shared back-end Host OS failures can create system-wide outages
- Can't provide a virtual instance of windows on a Linux Server
- Uneasy co-existence with VMs in the long haul
- Much as Containers give each app running on a server its own isolated environment to run, but those containers all share host servers' OS With severe dependencies.

VMs vs. Containers

Metric	VM	Containers
Infrastructure	 100s of VMs can be put on a single host server each running an application w its own Guest OS Strong Management systems available to deal with 100s of VMs per server 	 Lightweight, require Less Memory space Fast Launch time 1000s of containers can be loaded onto a Host. Containerized apps share Host OS's kernel to execute work Containers can become ultimate form of compute intensive low power, dense computing environment
Performance	 Slower than Containers since need to retrieve 10-20 GB of OS from storage per VM launch 	 Fast creation without shackle of retrieving OS Workload in Containers use Host OS kernel Container can boot up in 0.5 seconds Activates code instantly to test or launch add'l ecommerce capacity
Interoperability	 Systems designs fully compatibility with existing operations of enterprise DCs 	 Apps are formatted in a standard way to be placed in a container. Once in a container, each type of app moves around the network in same way
Maturity	 Robust, Highly Developed Proven, even in mission critical workloads 	 Less Mature Kinks not worked out yet Cos. Still working on a creative Management System

VMs vs Containers Characteristics 2

Metric	VM	Containers
Security	 Security of a dedicated OS Harder Logical Boundaries Hypervisor controlled dedicated pathway between App/Guest OS and Physical Infrastructure 	 High security concerns Containers share CPU, Memory, Disk in close proximity to each other Containers talk to each other using shared memory - one container can steal neighbor's data or spread its malicious code to neighbors
Portability	 Highly portable between systems running same hypervisor (such as ESX, Hyper-V, Xen or KVM) 	 Highly portable but bound to a certain version of an OS. An app inside a container can't move to another host OS, only where there is copy of same OS w same version level
Multi-tenancy	 VM's Guest OS can be different than physical host's OS allowing different types of Apps (Technical on Mac vs Marketing on Windows) to run on same Physical Host 	 Higher Level isolation with many apps running under the host OS and all containers sharing certain OS's kernel and certain Libs Proven barriers to keep containers colliding each other Once in a container, each type of app moves around the network in the same way

SN

VMs vs Containers Characteristics 3

Metric Containers VM **Architecture** • VMs package files that can • Built in layers and accessed independently.- a code change move from one host to affecting one layer can be executed without touching other another over internal layers, making changes less dangerous vs. monolithic networks or internet architecture in which an error can stall whole application • Big apps can be broken into smaller ones running in their own containers, maintained & upgraded independently Google/Kubernetes for Docker Manages multi-containers adoptable by enterprises running clusters of containers for large apps across multiple computers. Adoption & • Highly Developed and • Google's efforts to get container in Linux kernel & Docker adopted in 50-60% of all making its creation & movements in open source helped **Futures** large IT shops developers rally around them as a standard, avoiding • Robust, proven, even in proliferations mission critical workloads • Docker formatting engine now a standard with lots of tools/ • Multiple offerings by several workflows • ByYE2014 -100 million downloads, 730 contributors vendors • Being adopted as the • Support from Linux startups and large companies (IBM, MS, foundation in next RH, Docker, Google etc.) generation DCs and Clouds IBM Docker Hub Enterprise with Middleware allowing via Software Defined Data developers install preformatted dockerized containers in their won DCs and invoke the services through a link. Centers SDDC – SDC/SDS/ **SDN** • Stack multiple micro-services on a host using containers

18

- Stable core
- All major Linux platforms and distributions
- Execution engine plug-ins: LXC, libcontainer
- Filesystem plug-ins: AUFS, BTRFS, device mapper \diamond
- Host networking, link hostnames \diamond
- boot2docker: Mac OS X and Windows
- Support for SELinux and AppArmor \diamond
- TLS auth, systemd slices, release hashes

Distributed Applications

mongoDB

Official Repositories

- DBs, Web servers, OSes and more
- Free on Docker Hub Registry
- Optimized and tuned for Docker
- Maintained and supported
- Publisher program

Open Source Community

Containers – In Perspective

- Containers extending virtualization to next generation computing bringing in speed with thousands of containers launch able within seconds on same hardware lowering CapEx and OpEx for enterprises and cloud service providers.
- Several start-ups and all major IT vendors endorsing it.
- Allows developers to quickly create, ready-torun "containerized" applications and enterprises to offer preconfigured, ready to run infrastructure apps to VARs and System Integrators to add industry vertical apps
- Makes managing and deploying applications much easier
