Video Encoding Alternatives Compared: Density and Power

September 23-26, 2019

San Jose, CA

SDC¹⁹

Approximated infrastructure required for
80x 1080p30 Encoding Streams, or
40x Typical Encoding Ladders.

Implementation of Video Encoding using NVMe

Solution Requirements

Santa Clara, CA

SDC¹⁹

- Fast time to market to capture fast moving live video market
- Needs to use robust, highly tested infrastructure as much as possible
- Needs to be deployable quickly by customers

Why use a storage form factor?

- Using storage interface allows scaling using standard server infrastructure
- Transcending U.2 modules plug into SSD slots of NVMe Server

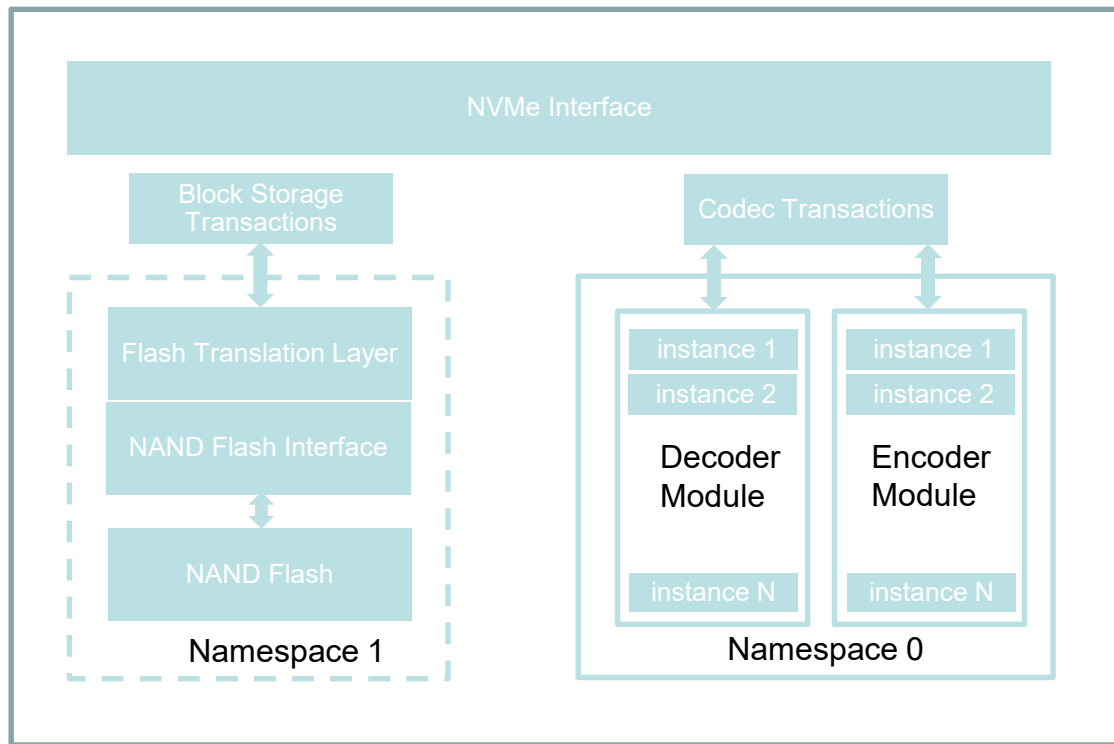

Why use NVMe?

- Easily combine storage and video into the same PCI-Express Interface
- Leverage significant amount of industry investment in NVMe
 - Kernel
 - Drivers
 - Hardware

Application of NVMe to control SSD and video processing

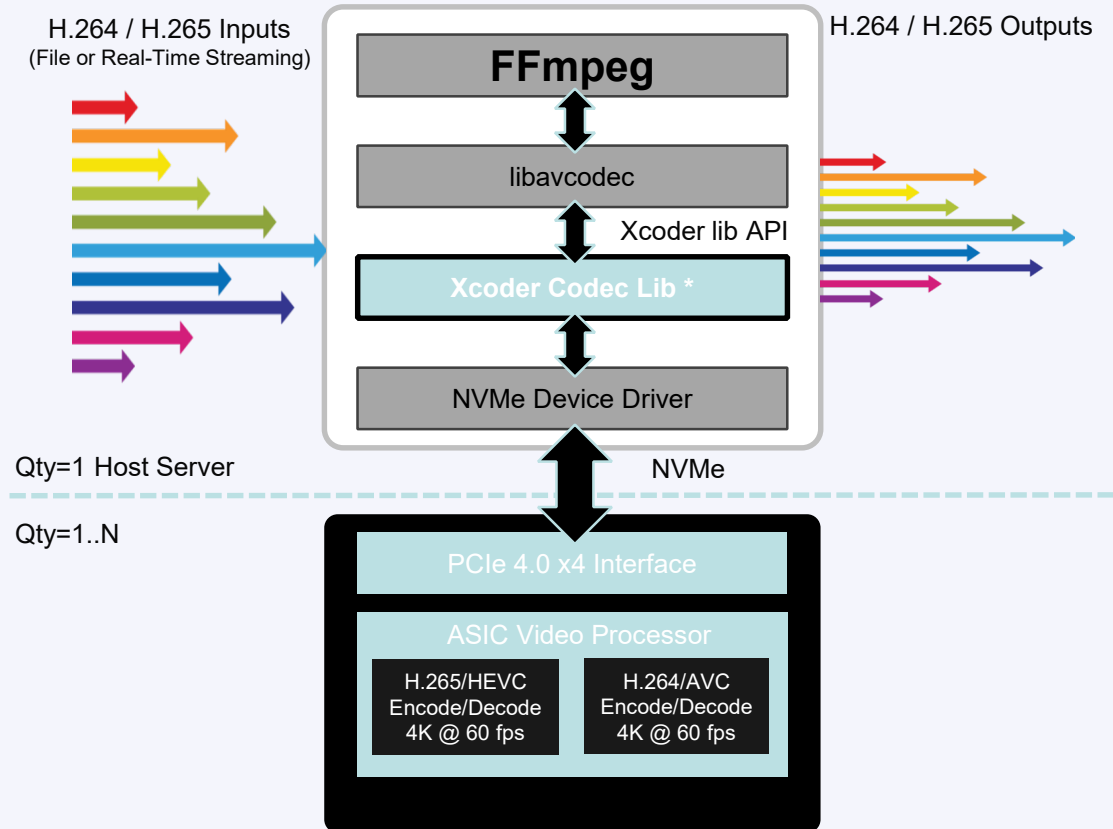

September 23-26, 2019

SDC¹⁹

Video Transcoder – Software Integration

- FFmpeg integration achieved by installing FFmpeg Codec Lib and SDK into host server
 - Seamlessly abstracts FFmpeg video transcoding functions from 1 or more transcoder modules
- Video transcode functions controlled through standard NVMe protocol

Vendor Specific Commands

- Vendor specific commands allow a “simpler” implementation
 - Advantages:
 - Simple to architect
 - Simple to implement
 - Challenges:
 - IOCTL path in kernel/driver is not optimized for performance
 - Requires administrative privileges
 - Windows only recently supported vendor specific commands and behavior does not match Linux
 - Is not currently supported by NVMe over Fabrics

Types of commands

Santa Clara, CA

Command	Encoder
Xcoder Open	Open a decoder/encoder instance
Xcoder Close	Close a decoder instance
Xcoder Query	Query xcoder for current status
Xcoder Write	Transfers data from host to codec for decode/encode
Xcoder Read	Transfers data from codec to host for decode/encode

Example Command Structure

Command:

Opcode	CDW10	CDW...	CDW15
--------	-------	--------	-------

Response:

DW0

- Xcoder Open – Opcode 0xC1
 - CDW10: Xcoder ID, configuration data
 - Completion: Xcoder instance
- Xcoder Write – Opcode -0x83
 - CDW10: Decoder id, instance, format and stream
 - CDW11: Size of data

IO Commands for video

- IO commands (block level read write) allow high speed access
 - Advantages:
 - Kernel is highly optimized for block level access
 - Very low latency, high priority
 - LBA structure does not align with the structure of our data
 - Need to “hack” the usage for our device, create new definitions of LBA regions, and access patterns
 - No ability within the command to send configuration information

Codec Directly Interacting with Storage

- Challenges with direct interaction:
 - SSD is LBA based but applications are file based
 - How will the internal SSD know the file system of the OS above?
- Without significant changes at the application layer / OS layer direct storage is not practical
- Requires standardization and changes to kernel for optimal solution

Challenges with Memory Management

- Memory movement is the largest contributor of CPU cycles with this solution
- IOCTL Challenges with Memory Management:
 - IOCTL will perform a memory copy if data is not 512 Byte aligned
 - Memory copy consumes significant CPU usage
- Need to optimize overall memory movement from library to host systems

Managing SSD and Video Together

September 19
Santa Clara, CA

- Video codec and SSD compete for same resources
- Need to guarantee quality of service for both SSD and transcoder
- How to guarantee QOS?

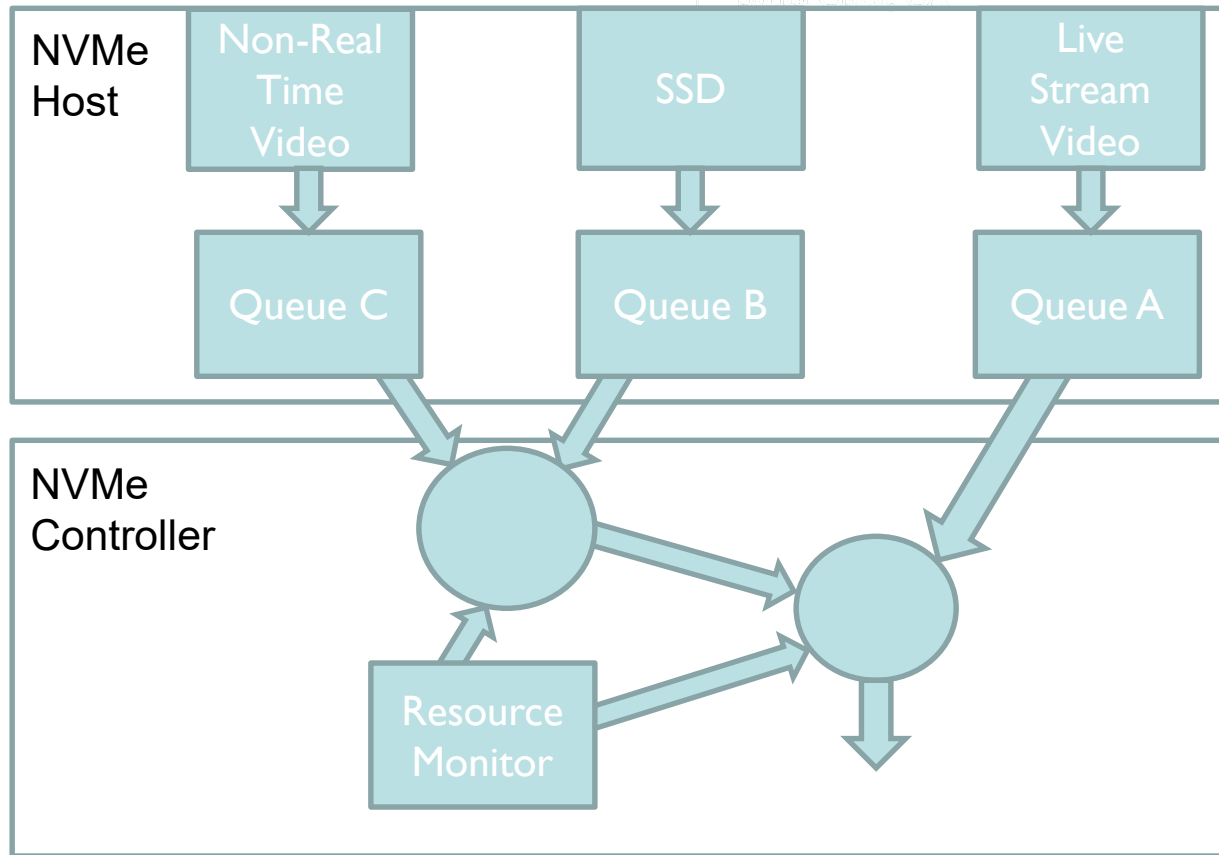

QOS Criteria / Prioritization

Santa Clara, CA

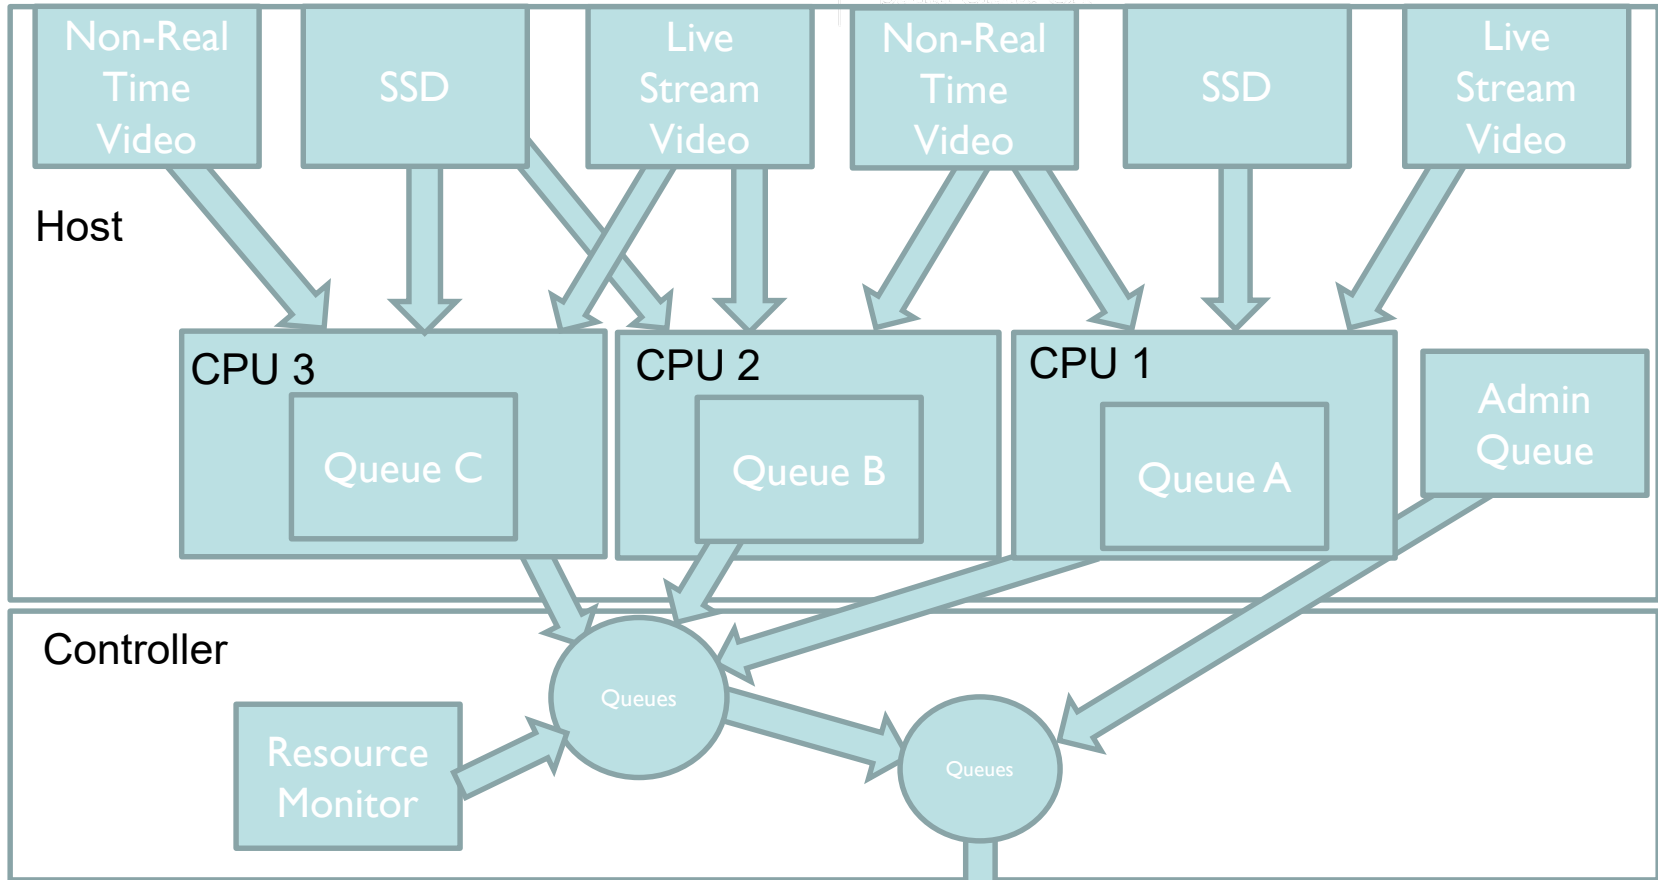

SDC¹⁹

- Live stream / real time video
 - Requires uninterrupted service and guaranteed frame rate (i.e. 30fps)
- SSD
 - Requires predictable performance
 - Requires QOS (including 99.99% latency)
- Best effort encoding (Non-Real-time)

Queues for Priority Management

Priority Management Internal

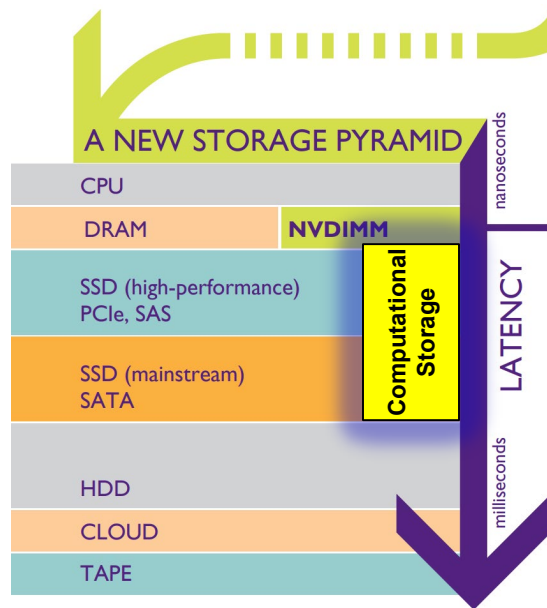

Why we need to Standardize Computational Storage?

September 23-26, 2019

SDC¹⁹

- Both vendor specific and block command approach with current NVMe is sub-optimal
 - Is a better approach possible?
- Should rethink OS queues for computational storage.
 - Should computational storage elements get a different queue?
- Items like identification, classification provide host system more information
 - Look like a formal device to host with exposed functionality
- Can we build the hooks to allow file based interactions without host interactions?

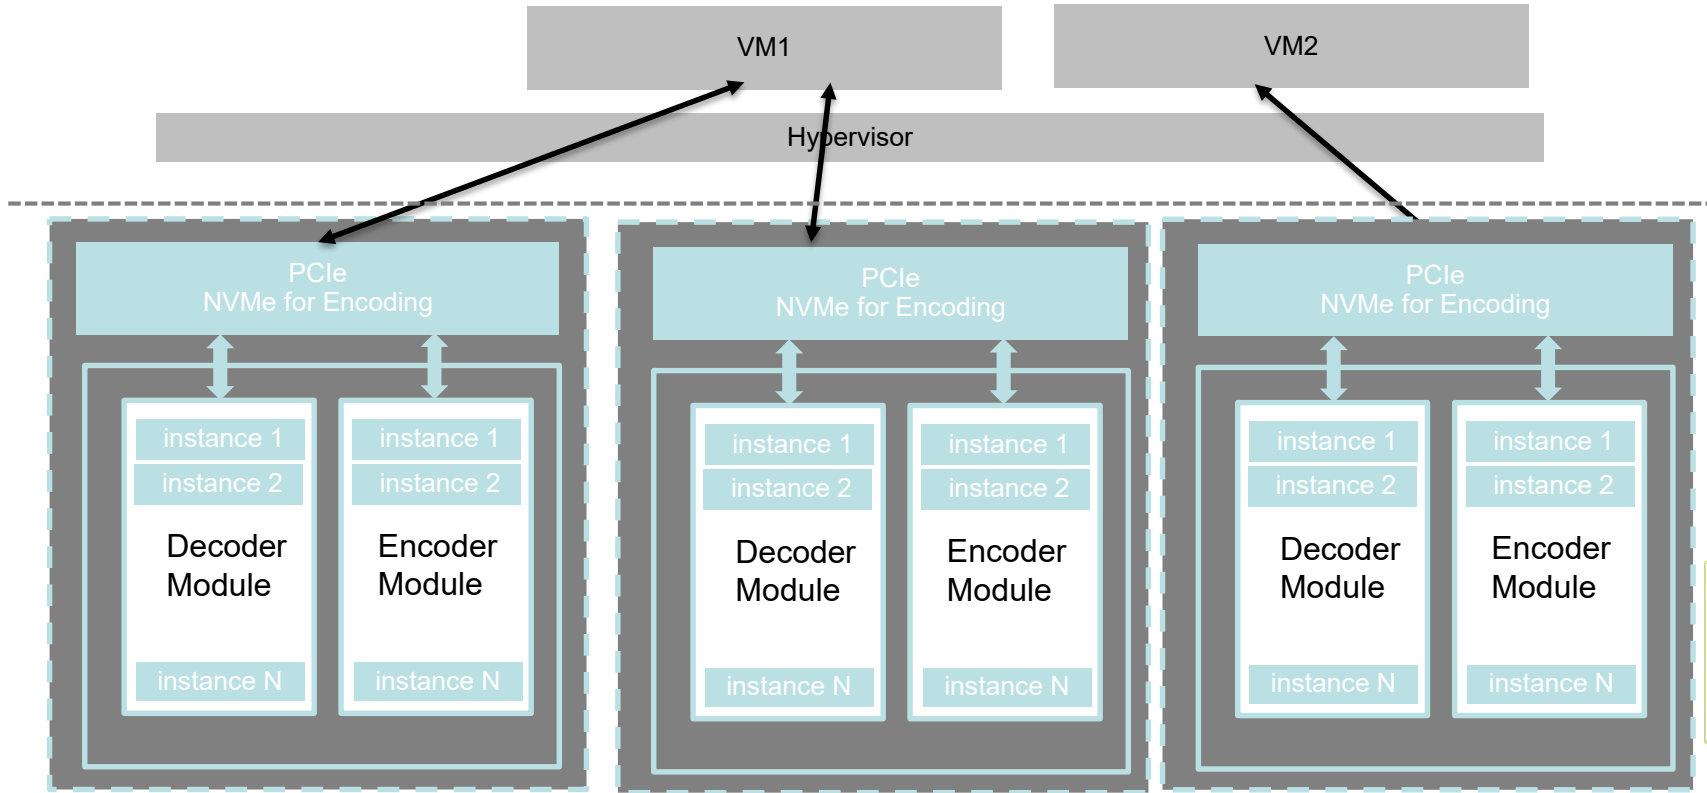

Scaling Video Encoding in the Cloud

Scaling-out Video Transcoding with NVMe-Over-Fabrics

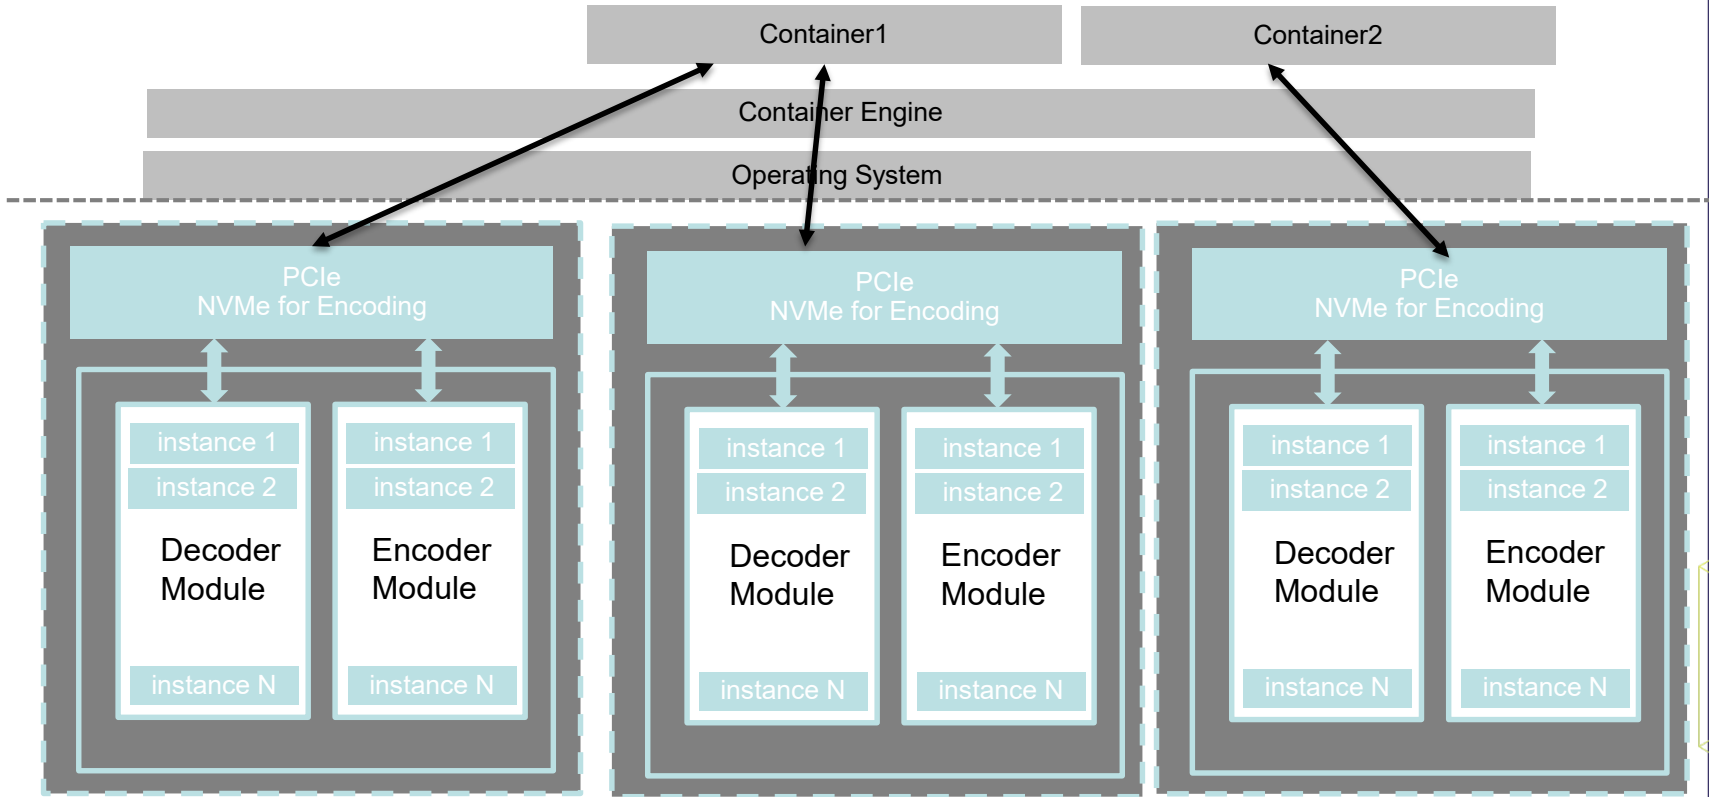

- Work with proven NVMe and NVMe-oF device drivers
- Composable infrastructure
- Just a Bunch of Transcoders (JBOT)
- Sharing video transcoding resources among servers

Virtualization for Cloud – Hypervisor

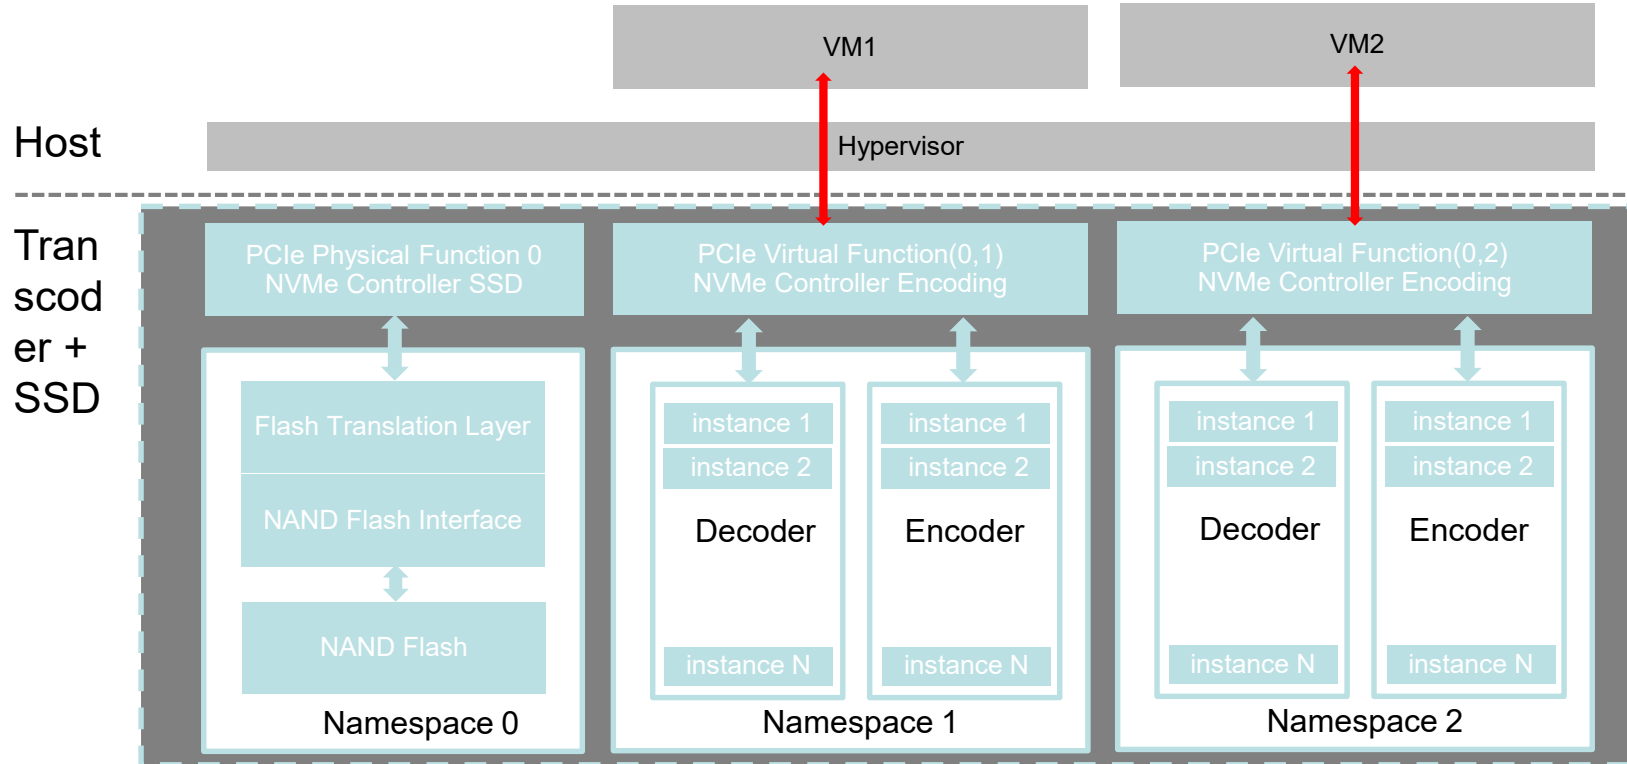

Virtualization for Cloud – Containers

Virtualization for Edge with SR-IOV

Share One among Virtual Machines
