# Persistent Memory in New Forms and Architectures With CXL

Presented by : Pekon Gupta, SMART Modular Technologies

# Reducing System Downtime

Incident → Detection → Containment → Recovery → Test and Repair

-  Malicious hack
-  Network Outage
-  Buggy code or misconfiguration

System back Online

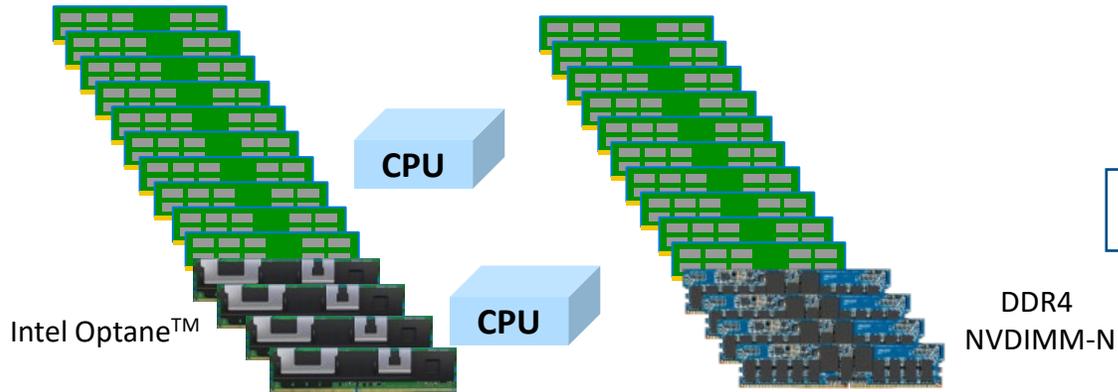

- Limiting the Blast Radius
- Rollback or stage intermediate transaction
- Distribute load

- Record real-time Error logs and security events.
- Preserve transactions in flight.
- Retrieve back up.

# Form-factors for Persistent Memory

## Persistent Memory in DIMM form-factor

- Low latency as directly attached to processor bus
- CPU and Platform dependent.
- Memory capacity limited by Thermal and PCB.
- May bring down the performance of entire DDR channel if not running at speed with other DIMM.

## Persistent Memory in EDSFF (E1.S or E3.S)

- CPU and Platform Agnostic
- Scalable and Hot pluggable. Improves serviceability
- Capacity limited by Thermal and PCB space constrains

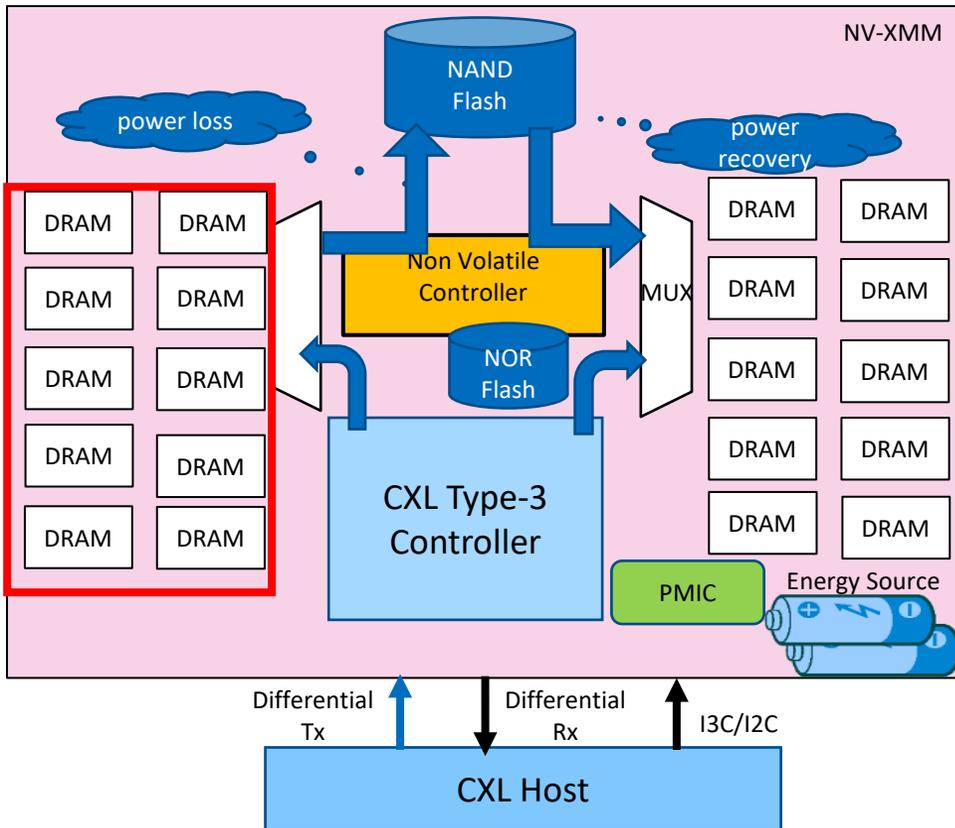

## Persistent Memory in PCIe CEM form-factor

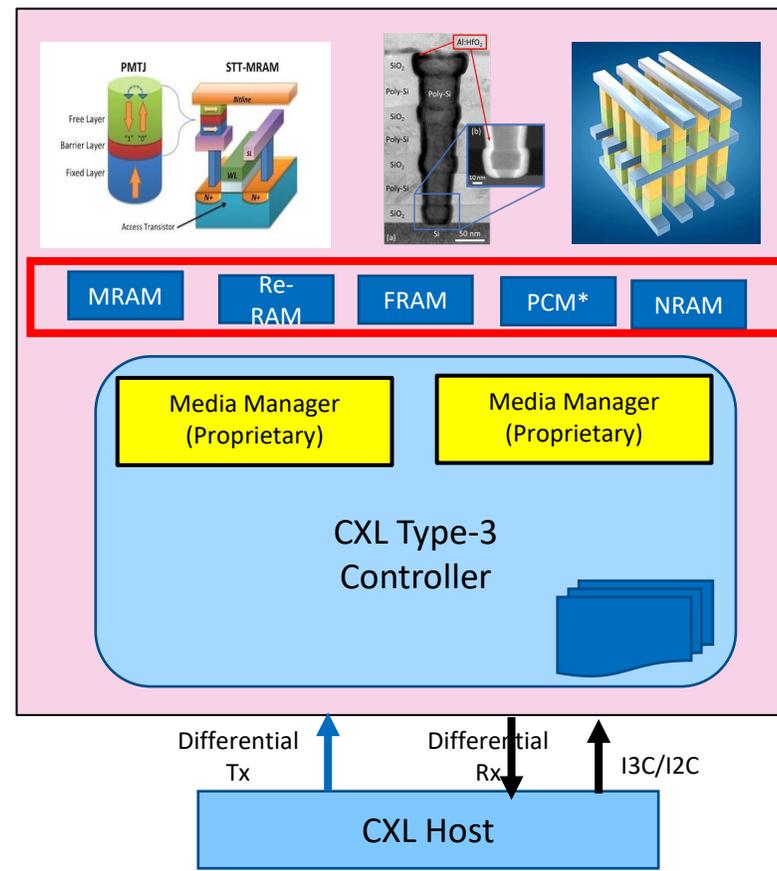

- CPU and Platform Agnostic
- Very High Memory capacity. (In Tera Bytes)
- Enables multi sourcing of DIMM and Technology.
- Limited serviceability. Hot Plugging not supported

# Persistent Memory Architectures with CXL

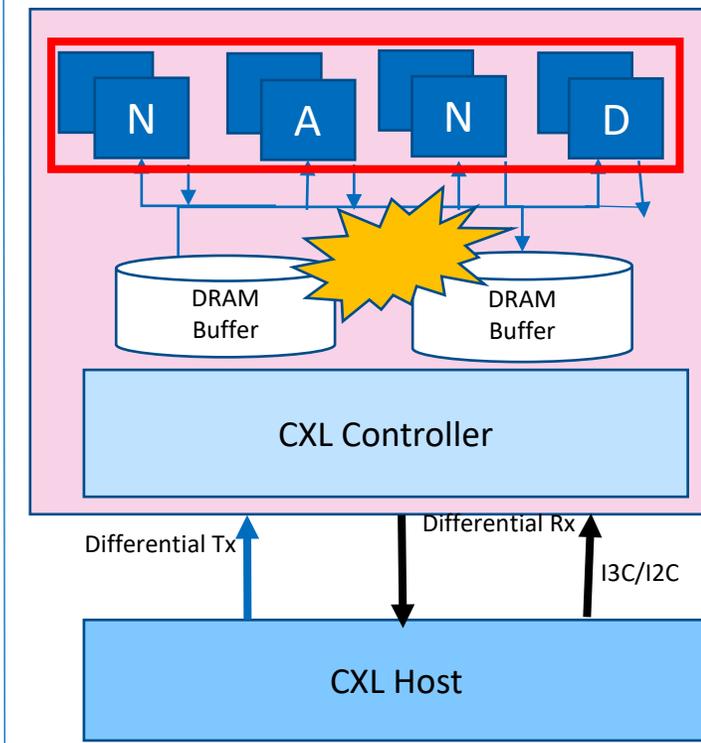

**DRAM backed by NAND  
(like NVDIMM-N)**

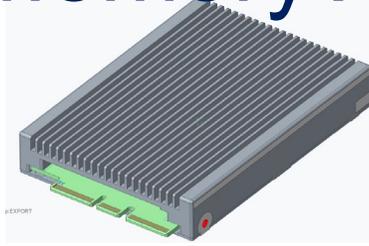

**Non-volatile media based  
(like NVDIMM-P or Intel Optane™ DIMM)**

**CXL based SSD  
(like NVDIMM-F)**

# Comparing Persistent Memory Architectures

	DRAM backed by NAND (like NVDIMM-N)	Non-Volatile Media based (like Intel Optane™ Pmem DIMM)	CXL based SSD (like NVDIMM-F)

# Take-away

- Persistent Memory reduces blast radius and Time to recovery.
- Select right Persistent Memory architecture to strike balance between Latency, Cost and Capacity.

- CXL™ is enabling Persistent Memory in new form-factors
