

STORAGE DEVELOPER CONFERENCE

SNIA ■ SANTA CLARA, 2015

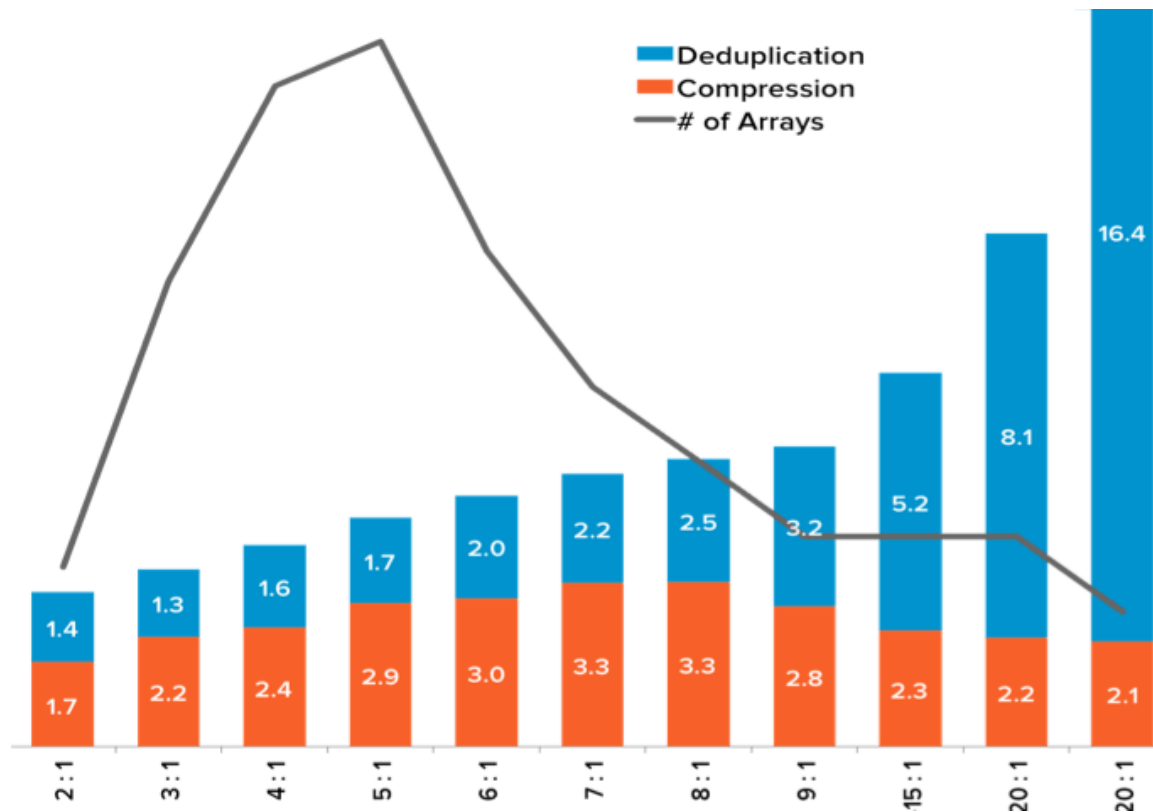

Design Decisions and Repercussions of Compression and Data Reduction in a Storage Array

Chris Golden
Pure Storage

Data Reduction

- ❑ Huge performance impact on disk
- ❑ Very little performance impact on flash
- ❑ Table stakes feature for all-flash storage arrays
- ❑ Goals
 - ❑ Increase usable capacity
 - ❑ Extend media lifetime
- ❑ Many different ways to implement
 - ❑ These design decisions have ripple effects

Dedup + Compression – Better Together

Actual results from entire Pure Storage install base

2X savings over 4KB dedupe alone

True data reduction, not thin provisioning

Dedup vs Compression

- ❑ Compression – A local process reducing the number of bits required to represent data
- ❑ Deduplication – A global process ensuring that identical data is only written once

Block Size + Alignment

- ❑ All arrays have 3 block sizes and alignments
 - ❑ Client, Array Device
- ❑ Size mismatches and/or unaligned operations create read / write amplification in the underlying layer
 - ❑ Client > Array > Device

Data Protection

- ❑ Our choice of data protection matters
 - ❑ Mirroring, RAID5, RAID6, etc.
- ❑ Should be designed with compression and deduplication in mind

Compression

- ❑ Reduces the number of bits required to represent the original data
- ❑ Final representation is variable sized
- ❑ We can apply more CPU for better results

Compression – How to Choose

- ❑ Variables to optimize
 - ❑ Compression Speed
 - ❑ Decompression Speed
 - ❑ Size of representation
- ❑ Variables that can be controlled
 - ❑ Choice of algorithm, level
- ❑ Variables that change with workload
 - ❑ Compressibility of the data

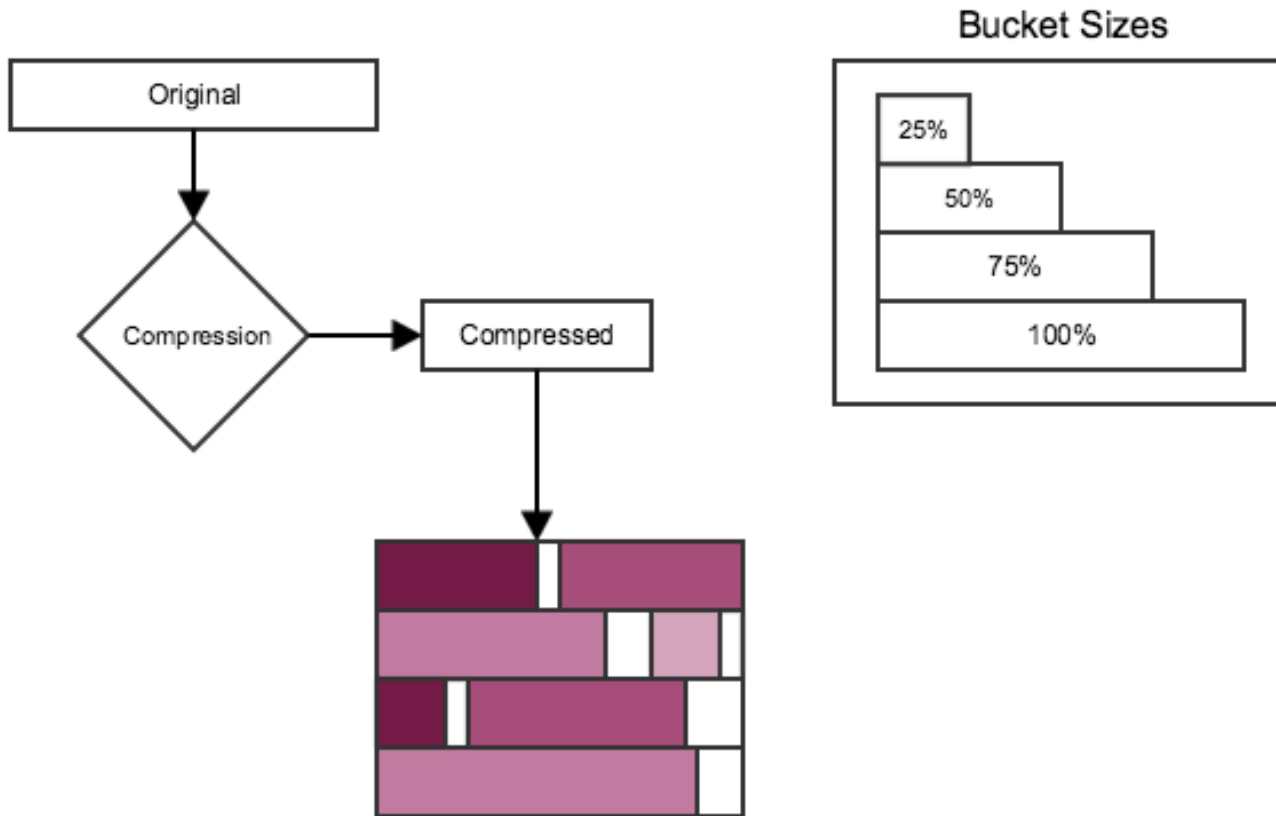

Compression – How to Store

- ❑ Full Precision
- ❑ Nearest Size Bins
- ❑ Large Bins with Many Blocks

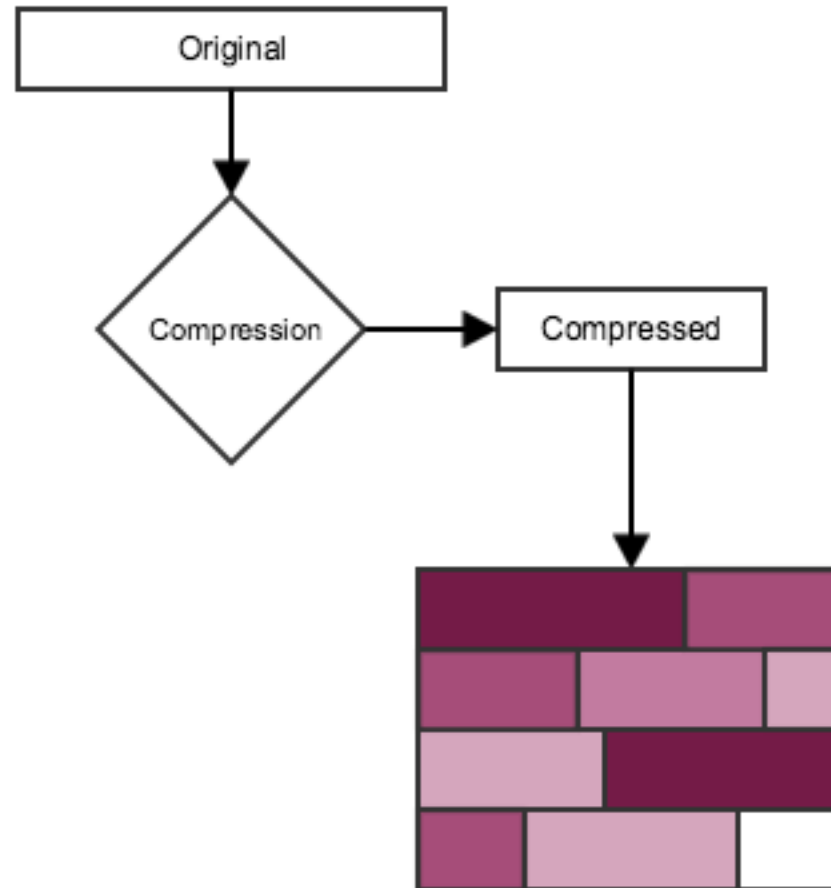

Full Precision

- ❑ Find free space on the underlying devices exactly matching the compressed size
- ❑ Global fragmentation problem
- ❑ Overwrites have 3 outcomes, 2 are bad
 - ❑ New data is larger, must find a new place
 - ❑ Data is smaller, extra space may be wasted

Details – Nearest Sized Bin

Details – Large Bins

Deduplication

- ❑ Identify duplicate bits and store them a single time
- ❑ Cryptographic Hash vs Weak Hash and Verify
- ❑ Fixed Size vs Variable Sized

Details – Cryptographic vs Weak Hash

- ❑ Cryptographic hash
 - ❑ More CPU required
 - ❑ More metadata required
- ❑ Weak Hash
 - ❑ Collisions must be resolved via device read

Details – Fixed vs Variable Size

- ❑ Fixed size
 - ❑ Fewer hashes to calculate
 - ❑ Alignment of user writes matters
- ❑ Variable size
 - ❑ More metadata required
 - ❑ Choice of compression becomes important

Variable Length Dedupe + Compression

- ❑ Creates read amplification and CPU overhead
 - ❑ Must read and decompress entire block
- ❑ Overwrites also get more complicated

- ❑ TODO: Add diagram

Compression + Dedupe

- ❑ Order of operations matters
- ❑ Compress first
 - ❑ Might require less CPU
 - ❑ Works well with fixed sized compression and dedupe
- ❑ Dedupe first
 - ❑ Can find duplicates in the middle of compressed blocks
 - ❑ Works well for variable dedup

Space Reporting

- ❑ Compression and dedup make space reporting complicated
- ❑ Hard problems
 - ❑ Identifying shared space and reporting
 - ❑ Predicting future capacity
 - ❑ How much space will I reclaim if I remove this data?
 - ❑ How much additional data can I store?

Performance

- ❑ We're skimming some performance off the top to enable greater space utilization
- ❑ Compression eats CPU cycles
- ❑ Dedup eats CPU cycles and may create hotspots
- ❑ Read / Write amplification

PLACEHOLDER - Analysis of a Sample Data Set

Wrap Up

- ❑ Different ways to implement data reduction
- ❑ Each implementation has implications on the rest of your system design
 - ❑ Performance
 - ❑ Economics
 - ❑ Ease of implementation

Thank You!
