ABSTRACT: This document describes a standardized method to assess the energy efficiency of commercial storage products in both active and idle states of operation. A taxonomy is defined that classifies storage products in terms of operational profiles and supported features. Test definition and execution rules for measuring the power efficiency of each taxonomy category are described; these include test sequence, test configuration, instrumentation, benchmark driver, IO profiles, measurement interval, and metric stability assessment. Qualitative heuristic tests are defined to verify the existence of several Capacity Optimization Methods. Resulting power efficiency metrics are defined as ratios of idle capacity or active operations during a selected stable measurement interval to the average measured power.

This document has been released and approved by the SNIA. The SNIA believes that the ideas, methodologies and technologies described in this document accurately represent the SNIA goals and are appropriate for widespread distribution. Suggestions for revisions should be directed to http://www.snia.org/feedback/.

Introduction

1 Introduction

There is broad awareness of the environmental impact of IT equipment use. This impact takes several forms: the energy expended in equipment manufacture and distribution, the impact of materials reclamation, and the energy consumed in operation and cooling of the equipment. IT equipment users of all kinds wish to make their IT operations as energy efficient as possible. This priority can be driven by one or more of several requirements:

- Rising energy costs have made power and cooling expenses a more significant percentage of total cost of ownership of server and storage equipment;

- Some data centers are physically unable to add more power and cooling load, which means that new applications and data can only be brought on if old ones are retired or consolidated onto new, more efficient configurations;

- Increased regulatory and societal pressures provide incentives for companies to lower their total energy footprints. For many companies, IT is a significant portion of overall energy consumption, and corporate Green goals can only be achieved by reducing IT’s energy needs or by making operations more efficient.

IT equipment users are seeking advice on the most energy efficient approach to getting their work done. It is not practical for customers to test a wide range of storage products and architectures for themselves. A more effective approach is to create a collection of standard metrics that allow IT architects to objectively compare a range of possible solutions. This objective, metric-based approach has a dual impact:

- Users can select the mode of storage usage that accomplishes their work objectives with the lowest overall energy consumption;

- Companies are being driven to innovate and compete in the development of energy efficient products as measured by the standard yardsticks.
2 Scope

2.1 Abstract

This document describes a standardized method to assess the energy efficiency of commercial storage products in both active and idle states of operation. A taxonomy is defined that classifies storage products in terms of operational profiles and supported features. Test definition and execution rules for measuring the power efficiency are described; these include test sequence, test configuration, instrumentation, benchmark driver, IO profiles, measurement interval, and metric stability assessment. Qualitative heuristic tests are defined to verify the existence of several Capacity Optimization Methods. Resulting power efficiency metrics are defined as ratios of idle capacity or active operations during a selected stable measurement interval to the average measured power.

2.2 Introduction

This document defines methodologies and metrics for the evaluation of the related performance and energy consumption of storage products in specific active and idle states.

Storage products and components are said to be in an “active” state when they are processing externally initiated, application-level requests for data transfer between host(s) and the storage product(s). For purposes of this document, idle is defined as “ready idle”, in which storage systems and components are configured, powered up, connected to one or more hosts and capable of satisfying externally initiated, application-level initiated IO requests within normal response time constraints, but no such IO requests are being submitted.

2.3 Current Revision

This document addresses storage products supporting block or file data access. Block access and file access refer to the type of service provided typically by Storage Area Network (SAN) and Network Attached Storage (NAS) systems, respectively. It is not appropriate to use this document to ascertain power efficiency for anything other than these two access modes. This document includes:

- A generalized taxonomy for storage products (clause 5) that addresses solid state, magnetic disk, tape library, and virtual media library products;
- An assessment mechanism for Capacity Optimization Methods (clause 6);
- Measurement and data collection guidelines for assessing the power efficiency of block- and file-based storage products in both active and ready idle states (clause 7);
- Metrics describing storage product power efficiency (clause 8);
- Required disclosures for a test result published as a SNIA Emerald™ Power Efficiency Measurement test result (clause 9).

2.4 Purpose of a SNIA Emerald™ Power Efficiency Measurement test result

The purpose of a SNIA Emerald™ Power Efficiency Measurement test result is to provide a reproducible and standardized assessment of the energy efficiency of commercial storage products in both active and ready idle states. Therefore:

1. Tested systems shall be comprised of commercially released or soon to be released products and components;

---

1 SNIA Emerald™ is a trademark of the Storage Networking Industry Association.
Scope

2. Tested systems shall employ settings, parameters, and configurations that would allow end-users to achieve power efficiency levels equivalent to the published result;

3. All data published as an SNIA Emerald™ Power Efficiency Measurement test result shall be gathered from test execution conducted according to this document;

4. Test execution shall complete in its entirety and without test failure or test error messages;

5. Software features which invoke, generate, or use software designed specifically for the test shall not be used. Configuration options chosen for test execution shall be options that are generally recommended for the customer;

6. Energy for powering the equipment shall be provided by the power mains that are being monitored (not by an internal UPS).

A SNIA Emerald™ Power Efficiency Measurement shall be a good faith effort to accurately characterize the power requirements of the tested system. The precise configuration used in a SNIA Emerald™ Power Efficiency Measurement is left to the sponsor of a test. Any commercially released or soon to be released components may be used, and a focus on new or emerging components or technologies is encouraged.

2.5 Disclaimer

A SNIA Emerald™ Power Efficiency Measurement test result provides a high-level assessment of the energy efficiency of the tested system in specific ready idle and active states. It is not an attempt to precisely model or reproduce any specific installation.

Actual performance and energy consumption behavior is highly dependent upon precise workload, environmental and usage parameters. While a SNIA Emerald™ Power Efficiency Measurement test result is intended to provide a realistic and reproducible assessment of the relative power efficiency of a system across a broad range of configurations and usage patterns, it cannot completely match the precise needs of any one specific installation.

4 Definitions, Symbols, Abbreviations, and Conventions

4.1 Overview

For the purposes of this document, the terms and definitions given in The SNIA Dictionary[2] and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

• ISO Online browsing platform: available at https://www.iso.org/obp
• IEC Electropedia: available at http://www.electropedia.org/

The terms and definitions defined in this document are based on those found in The SNIA Dictionary[2]. They have been extended, as needed, for use in this document. In cases where the current definitions in the SNIA dictionary conflict with those presented in this document, the definitions in this document shall apply.

4.2 Definitions

4.2.1 auto-tiering

policy-based system that automatically places and moves data across tiers to optimize performance service levels, cost targets, and overall energy consumption

Note 1 to entry: Each storage tier may comprise different storage technologies, offering varying performance, cost, and energy consumption characteristics.

4.2.2 cache

temporary data storage, not directly addressable by end-user applications, used to store data for expedited access to or from slower media

4.2.3 Capacity Optimization Method (COM)

subsystem, whether implemented in hardware or software, which reduces the consumption of storage space required to store a data set

4.2.4 committed data

data that has been written to stable storage

4.2.5 compression

the process of encoding data to reduce its size
4.2.6

**count-key-data (CKD)**

disk data organization model in which the disk is assumed to consist of a fixed number of tracks, each having a maximum data capacity

Note 1 to entry: The CKD architecture derives its name from the record format, which consists of a field containing the number of bytes of data and a record address, an optional key field by which particular records can be easily recognized, and the data itself.

4.2.7

**data deduplication**

replacement of multiple copies of data—at variable levels of granularity—with references to a shared copy in order to save storage space and/or bandwidth

4.2.8

**dedupable**

property that a collection of data is said to possess if the needed storage capacity for the data is reduced significantly by data deduplication

4.2.9

**delta snapshot**

type of point in time copy that preserves the state of data at an instant in time, by storing only those blocks that are different from an already existing full copy of the data

4.2.10

**direct-connected**

storage designed to be under the control of a single host, or multiple hosts in a non-shared environment

4.2.11

**efficiency**

ratio of useful work to the power required to do the work

4.2.12

**file**

abstract data object made up of a) an ordered sequence of data bytes stored on a disk or tape, b) a symbolic name by which the object can be uniquely identified, and c) a set of properties, such as ownership and access permissions that allow the object to be managed by a file system or backup manager

4.2.13

**file system**

software component that imposes structure on the address space of one or more physical or virtual disks so that applications may deal more conveniently with abstract named data objects of variable size (files)
4.2.14
**fixed block architecture (FBA)**
model of disks in which storage space is organized as linear, dense address spaces of blocks of a fixed size
Note 1 to entry: Fixed block architecture is the disk model on which SCSI is predicated.

4.2.15
**fixed content addressable storage (FCAS)**
storage optimized to manage content addressable data that is not expected to change during its lifetime

4.2.16
**formatted capacity**
total number of bytes available to be written after a system or device has been formatted for use, e.g., by an object store, file system or block services manager
Note 1 to entry: Formatted capacity is less than or equal to raw capacity. It does not include areas set aside for system use, spares, RAID parity areas, checksum space, host- or file system-level remapping, "right sizing" of disks, disk labeling, caches, file system metadata, and so on. However, it may include areas that are normally reserved—such as snapshot set-asides—if they can alternatively be configured for ordinary data storage by the storage administrator.

4.2.17
**free space**
amount of additional irreducible data that can be written to the product under test as configured

4.2.18
**hot band**
simulation of naturally occurring areas of storage address space accessed more frequently than is typical

4.2.19
**hybrid Solid State Storage and magnetic disk system**
storage system whose formatted capacity is provided by a combination of Solid State Storage and magnetic disk storage devices

4.2.20
**hyper converged system**
software-defined set of resources with at least two of the following: compute, storage, networking and/or virtualization

4.2.21
**IO intensity**
measure of the number of IOPS requested by a load generator
Note 1 to entry: IO intensity is phrased as a percentage of selected maximum IOPS level that satisfies the timing requirement(s) for a taxonomy category.
4.2.22
irreducible data
data that is neither compressible nor dedupable

4.2.23
JBOD
shelf that does not provide storage protection
Note 1 to entry: A JBOD is a “simple” “just a bunch of disks,” an architecture that does not provide storage protection capabilities. The storage devices of a JBOD can function as individual volumes or can be combined to form a single logical volume by a simple controller. A JBOD provides no redundancy or resilience, so failure of a single storage device amounts to failure of a whole logical volume. A JBOD is a single shelf.

4.2.24
load generator
hardware and software environment executing the workload generator to drive the product under test during measurements

4.2.25
Logical Unit (LU)
entity within a SCSI target that executes IO commands

4.2.26
Logical Unit Number (LUN)
synonym for logical unit

4.2.27
Maximum Time to First Data (MaxTTFD)
maximum time required to start receiving data from a storage system to satisfy a read request for arbitrary data

4.2.28
network-connected
storage designed to be connected to a host via a network protocol (e.g., TCP/IP, IB, and FC)

4.2.29
non-disruptive serviceability
support for continued availability of data during all service operations
Note 1 to entry: Examples of non-disruptive serviceability are FRU replacement, code patches, software/firmware upgrades, configuration changes, data migrations, and system expansion done during production time.
Note 2 to entry: Service operations may result in performance impacts to data availability, but will not result in a loss of access.
Definitions, Symbols, Abbreviations, and Conventions

4.2.30

non-volatile
the property of retaining data in the event of the loss of power

4.2.31

parity RAID
collective term used to refer to Berkeley RAID Levels 3, 4, 5 and 6

4.2.32

permanent storage
data storage media which can retain data indefinitely without a power source

4.2.33

product under test
customer-orderable system or component that is the subject of a SNIA Emerald™ Power Efficiency Measurement

4.2.34

raw capacity
sum of the raw, unformatted, uncompressed capacity of each of the storage device in the product under test

4.2.35

ready idle
operational state in which a system is capable of satisfying an arbitrary IO request within the response time and MaxTTFD constraints of its selected taxonomy category, but no user-initiated IO requests are being submitted to the system

Note 1 to entry: In the ready idle state, background I/O activity, autonomously initiated by the solution under test, may take place

4.2.36

sequential read
IO load consisting of consecutively issued read requests to logically adjacent data

4.2.37

sequential write
IO load consisting of consecutively issued write requests to logically adjacent data

4.2.38

shelf
modular enclosure suitable for installation in a rack

Note 1 to entry: A shelf typically houses storage devices, storage controllers, power supplies, and cooling devices. A shelf typically has a pre-wired backplane that carries power and I/O interconnect signals to the housed components.
4.2.39
**Single Point of Failure (SPOF)**

one component or path in a system, the failure of which would make the system inoperable or data inaccessible

4.2.40
**SNIA Emerald™ Power Efficiency Measurement**

test performed according to this document

4.2.41
**SNIA Emerald™ Power Efficiency Measurement test result**

result of a test performed according to this document

4.2.42
**Solid State Storage**

storage capability built from non-volatile solid state electronic devices

4.2.43
**solution under test**

all hardware and software components that are exercised during a test to verify functional behavior or determine performance characteristics, including all of the hardware and software components involved in a test

Note 1 to entry: It includes the physical and virtual components of the load generator, storage media, and the entire data path between the load generator and the storage media.

4.2.44
**stable storage**

storage that maintains data across power failures or other transient failures

Note 1 to entry: See Annex C.

4.2.45
**storage controller**

device for handling storage requests that includes a processor or sequencer programmed to autonomously process a substantial portion of IO requests directed to storage devices

4.2.46
**storage device**

collective term for disk drives, solid state drives and modules, tape cartridges, and any other mechanisms providing non-volatile data storage

Note 1 to entry: This definition is specifically intended to exclude aggregating storage elements such as RAID array subsystems, robotic tape libraries, filers, and file servers. Also excluded are storage devices which are not directly accessible by end-user application programs, and are instead employed as a form of internal cache.
Definitions, Symbols, Abbreviations, and Conventions

4.2.47
storage protection
any combination of hardware and software (e.g., RAID, NVRAM, disk sparing and background disk scrubbing or media scan) that assures that all completed IO operations will be preserved in the event of power loss or storage device failure

4.2.48
system crash
hardware or software failure which causes data to be temporarily unavailable and which requires a reboot of one or more hardware components and/or re-initialization of one or more software components in order for data access to be restored

4.2.49
test sponsor
individual, company, or agent that performs a test according to this document

4.2.50
thin provisioning
technology that allocates the capacity of a volume or file system as applications write data, rather than pre-allocating all the capacity at the time of provisioning

4.2.51
virtual drive
removable media storage device, e.g., tape drive, that is emulated using other storage devices

4.2.52
workload generator
software used in the load generator to drive the product under test during measurement

4.3 Symbols and Abbreviated Terms
CKD     Count-Key-Data
COM     Capacity Optimization Method
FBA     Fixed Block Architecture
FCAS    Fixed Content Addressable Storage
FRU     Field-Replaceable Unit
INCITS  InterNational Committee for Information Technology Standards
IT      Information Technology
LU      Logical Unit
LUN     Logical Unit Number
MAID    Massive Array of Idle Disks
MaxTTFD Maximum Time to First Data
NVRAM   Non-Volatile Random Access Memory

### 4.4 Expression of Provisions

This document uses the verbal forms for expressions of provisions as defined by ISO/IEC Directives Part 2 (Eighth edition, 2018). These verbal forms include shall, shall not, should, should not, may, may not, can, cannot, and must.

### 4.5 Conventions

Storage capacities are represented in base-10. IO transfer sizes and offsets are represented in base-2. The associated units and abbreviations used in this document are:

- A kilobyte (KB) is equal to $10^3$ B.
- A megabyte (MB) is equal to $10^6$ B.
- A gigabyte (GB) is equal to $10^9$ B.
- A terabyte (TB) is equal to $10^{12}$ B.
- A petabyte (PB) is equal to $10^{15}$ B.
- An exabyte (EB) is equal to $10^{18}$ B.
- A kibibyte (KiB) is equal to $2^{10}$ B.
- A mebibyte (MiB) is equal to $2^{20}$ B.
- A gibibyte (GiB) is equal to $2^{30}$ B.
- A tebibyte (TiB) is equal to $2^{40}$ B.
- A pebibyte (PiB) is equal to $2^{50}$ B.
- An exhibyte (EiB) is equal to $2^{60}$ B.
5 Taxonomy

5.1 Introduction

This clause defines a market taxonomy that classifies storage products or subsystems in terms of operational profile and supported features.

While this taxonomy is broad and defines a framework for products that range from consumer solutions to enterprise installations, it is not intended to address all storage devices. For example, this taxonomy does not address storage devices that rely on a Universal Serial Bus (USB) connection for their power.

Further, while this document includes definitions for its entire taxonomy, it does not include testing methodologies for the entire taxonomy.

The taxonomy is structured as a 3-level hierarchy of Set, Category, and Classification. A Set is a broad grouping of products. The Sets are: Disk Set, RVML (removable & virtual media library) Set, and NVSS (non-volatile solid state) Set. A Category is a grouping of products within a Set. The Categories are: Online, Near-Online, Removable Media Library, Virtual Media Library, Disk Access, and Memory Access. A Classification is a level of product sophistication, size, and complexity that corresponds to market delineations. Classifications are identified as a numeric suffix appended to a Category. Some Classifications are used within multiple Categories.

5.2 Taxonomy Sets

Taxonomy sets define broad groupings of storage products that share similar system characteristics. See Figure 1. Products in different sets are generally not comparable in performance or power efficiency characteristics.

![Taxonomy Overview Diagram]

5.3 Taxonomy Categories

5.3.1 General

Taxonomy categories define broad market segments within a Set that can be used to group products that share common functionality or performance requirements, and within which meaningful product
comparisons can be undertaken. This document defines six broad taxonomy categories (summarized in Table 2):

- Disk Set Online, defined in subclause 5.5;
- Disk Set Near-Online, defined in subclause 5.6;
- RVML Set Removable Media Library, defined in subclause 5.7;
- RVML Set Virtual Media Library, defined in subclause 5.8;
- NVSS Set Disk Access, defined in subclause 5.9;
- NVSS Set Memory Access, defined in subclause 5.10.

Within a taxonomy category, a specific model or release of a product will support different feature sets, whether focused on capacity, reliability, performance, functionality, or another differentiator. Feature and functionality differences within a category are addressed with attributes. Each taxonomy category defines a set of attributes that are common to all products within the category.

### 5.3.2 Category Attributes

Where a taxonomy category requires a specific, fixed setting or range for a given attribute, that setting is summarized in Table 2 to assist a test sponsor in initial category selection. The full set of attributes for each category is provided in subclauses 5.5 through 5.10.

### 5.4 Taxonomy Classifications

Classifications define combinations of settings or values for the attributes within a Category.

Taxonomy Classifications discriminate between different systems. The goal of the Classifications is to differentiate between systems of differing size, complexity, and target market. The Classifications are in general the following:

- Consumer/Component (<classification> 1),
Consumer (classification 1) systems are any of a wide array of manufactured goods which are purchased primarily for personal, family, household, or small-business purposes.

Components (classification 1) are components (e.g., a stand-alone tape drive or an individual hard disk drive) that are a part of a data-center storage product.

JBOD (classification 1.5) is a "simple" JBOD, an architecture that does not have storage protection capabilities built in. The storage devices in a JBOD can function as individual volumes or can be connected to form a single logical volume by a simple, integrated controller providing no redundancy. A JBOD provides no redundancy or resilience, so failure of a single storage device amounts to failure of a whole logical volume. A JBOD is a single shelf.

Low-end systems (classification 2) typically are a single shelf with one or two integrated controllers and limited expandability.

Mid-range (classification 3 and classification 4) systems are sub-divided into small and large mid-range systems. Small Mid-range systems (classification 3) generally have limited expandability and robustness compared to Large Mid-range systems (classification 4).

High-end (classification 5) and Mainframe (classification 6) systems are very large systems that can have very high capacity and offer a high level of robustness. Mainframe is differentiated from High End in that FBA/CKD support is required.

Table 3 provides an overview of the taxonomy classifications.

a Entries in this level of the taxonomy include both consumer products and data-center components, e.g., stand-alone tape drives.
b No test procedure for this Classification is provided by this document.
c Classification is not defined; no test procedure is provided by this document.

#### 5.5 Disk Set Online Category

The Disk Set consists of storage products based on rotating media devices, typically magnetic disks.

The Disk Set Online Category defines the features and functionalities for an online, random-access, rotating media-based storage product. Products in this profile may provide any combination of block, file, or object interfaces. Table 4 defines the requirements for the taxonomy classifications (Disk Set Online Online 1, etc.) defined in this category.
## Table 4 – Disk Set Online Classifications

</table>

<sup>a</sup> No test procedure for this Classification is provided by this document.

<sup>b</sup> There is no upper limit on the number of drives in any Classification.

### 5.6 Near-Online Category

The Disk Set consists of storage products based on rotating media devices, typically magnetic disks. The Disk Set Near-Online category defines the features and functionalities for a near-online, random-access rotating media-based storage product. Products in this profile employ MAID or FCAS architectures.
as well as any combination of block, file, or object interfaces. Table 5 defines the requirements for this taxonomy classifications (Disk Set Near-Online Near-Online 1, etc.) defined in this category.

Table 5 – Disk Set Near-Online Classifications

</tr>
</tbody>
</table>

<sup>a</sup> No test procedure for this Classification is provided by this document.

<sup>b</sup> Classification is not defined; no test procedure is provided by this document.

<sup>c</sup> There is no upper limit on the number of drives in any Classification.

5.7 RVML Set Removable Media Library Category

This category defines the features and functionalities for storage products that rely on automated or
manual media loaders (e.g., tape or optical libraries). Table 6 defines the requirements for the taxonomy classifications defined in this category.

Note: In this document, the Category name RVML Set Removable Media Library Category name is often expressed as simply Removable Media Library Category.

</tr>
</tbody>
</table>

<sup>a</sup> Classification is not defined; no test procedure is provided by this document.

<sup>b</sup> There is no upper limit on the number of drives.

5.8 RVML Set Virtual Media Library Category

This operational profile defines the features and functionalities for sequential-access storage products that rely on non-removable storage media to provide a Virtual Media Library. Table 7 defines the requirements for the taxonomy classifications (RVML Set Virtual Media Library Virtual 1, etc.) defined in this category.

Note: In this document, the Category name RVML Set Virtual Media Library Category name is often expressed as simply Virtual Media Library Category.
Table 7 – RVML Set Virtual Media Library Classifications

^a Classification is not defined; no test procedure is provided by this document.

^b There is no upper limit on the number of drives.

5.9 NVSS Set Disk Access Category

The NVSS Set consists of storage products based on non-volatile Solid State Storage.

The NVSS Set Disk Access Category defines the features and functionalities for an online, random-access, Solid State Storage-based disk access storage product. A storage product offers disk access if it provides data access using a storage paradigm, i.e., open, close, read, and write.

Products in this profile may provide any combination of block, file, or object interfaces. Table 8 defines the requirements for the taxonomy classifications (NVSS Set Disk Access Online 1, etc.) defined in this category.
### 5.10 NVSS Set Memory Access Category

The NVSS Set consists of storage products based on non-volatile Solid State Storage.
The NVSS Set Memory Access Category defines the features and functionalities for an online, random-access, Solid State Storage-based memory access storage product. A storage product offers memory access if it provides host access to storage using memory primitives, e.g., load and store.

Products in this profile provide a memory interface. Table 9 identifies the potential requirements for the taxonomy classifications in this category.

### 5.11 Classification Attributes

#### 5.11.1 Introduction

Classifications in all Sets and Category are distinguished by a set of attributes. This sub clause specifies the requirements for a product that has each of the attributes.

#### 5.11.2 Access Paradigm

Access Paradigm is one or more of Block, File, Object, and Memory.
A storage product having the Block Access Paradigm attribute shall provide fixed-block or CKD access to data, e.g., via SCSI block access for disks/tapes.

A storage product having the File Access Paradigm attribute shall provide file access to data, e.g., via the NFS protocol.

A storage product having the Object Access Paradigm attribute shall provide object access to data, e.g., via the SCSI OSD protocol (INCITS 400-2004 and INCITS 458-2011).

A storage product having the Memory Paradigm attribute shall provide access to data via CPU memory access instructions, e.g., load and store.

5.11.3 Access Pattern

Access Pattern is one or more of Random and Sequential.

A storage product having the Random Access Pattern attribute shall provide roughly equal access time to any stored data.

A storage product having the Sequential Access Pattern attribute may provide faster access to data at the address following the last accessed data than to other data.

5.11.4 Consumer/Component

A consumer product is any of a wide array of storage products which are used primarily for personal, family, household, or small-business purposes.

Components are devices (e.g., a stand-alone tape drive or an individual hard disk drive) that are a part of a data-center storage product.

A storage product having the Consumer/Component attribute shall have one of the above properties.

5.11.5 FBA/CKD Support

A storage product having the FBA/CKD Support attribute shall provide count-key-data as defined by IBM Corporation[3].

5.11.6 MaxTTFD

A storage product meeting the requirements of a given Classification/Category shall offer a MaxTTFD within the range specified in the associated Classification table.

5.11.7 Media Type

Media Type identifies the type of storage media providing the formatted capacity of a product. A storage product meeting the Media Type attribute shall include the type(s) of media specified in the associated Classification table.

The NVSS Set Disk Access Category Media Type “Solid State Storage + optional magnetic disk” encompasses either a purely Solid State Storage system or a hybrid Solid State Storage and magnetic disk system.

5.11.8 Multi-host Shareability

Multi-host Shareability identifies the number of hosts that can share the storage product. A storage product meeting the Multi-host Shareability attribute shall support the number of concurrently connected hosts given in the associated Classification table.

5.11.9 No SPOF

No SPOF is a storage product attribute. A storage product meeting the No SPOF attribute shall not have any component or path whose failure makes the system inoperable or data inaccessible.
5.11.10 Non-Disruptive Serviceability
Non-Disruptive Serviceability is a storage product attribute. A storage product meeting the Non-Disruptive Serviceability attribute shall support continued availability of data during all service operations, including FRU replacement, code patches, software/firmware upgrades, configuration changes, data migrations, and system expansion.

5.11.11 Robotics
A storage product having the Robotics attribute shall include an automatic mechanical system for loading and unloading storage media.

5.11.12 Stable Storage Support
A storage product having the Stable Storage Support attribute shall provide stable storage as specified by Annex C.

5.11.13 Storage Controller
A storage product having the Storage Controller attribute shall have a storage controller.

5.11.14 Storage Protection
A storage product having the Storage Protection attribute shall assure that all completed IO operations will be preserved in the event of power loss or storage device failure. This assurance can be provided by a combination of hardware and/or software, e.g., RAID, NVRAM, disk sparing, background disk scrubbing, and/or background media scan.

5.11.15 System Capacity

5.11.15.1 Introduction
System Capacity is a metric used to help discriminate between systems of different sizes.

5.11.15.2 Disk Set and RVML Set Classifications
For the Disk Set Online, Disk Set Near-Online, RVML Set Removable Media Library, and RVML Set Virtual Media Library Classifications, System Capacity is the number of storage devices supported by a storage product. A storage product meeting the System Capacity attribute shall support the number of storage devices within the specified range.

5.11.15.3 NVSS Set Disk Access Classification
For the NVSS Set Disk Access Classification, System Capacity is specified qualitatively as one of:

- consumer: A system marketed primarily for personal, family, household, or small-business purposes.
- JBOD: A single enclosure providing no storage protection.
- very small: An entry level system with relatively small capacity and limited expandability.
- small: An entry level system with relatively higher capacity and more expandability than the very small system.
- medium: A higher capacity system that may have higher expandability than the small capacity system and with significantly more capabilities than the small systems.
- large: A system with very high capacity and greater expandability compared to the medium and small systems intended for large Enterprises.
- mainframe: A large system intended for Mainframe applications.
An NVSS Set Disk Access Classification storage product meeting the System Capacity attribute shall meet the qualitative description given.

5.11.15.4 NVSS Set Memory Access Classification

For the NVSS Set Memory Access Classification, System Capacity is specified qualitatively as one of:

- **consumer**: A system marketed primarily for personal, family, household, or small-business purposes.
- **JBOD**: A single enclosure providing no storage protection.
- **very small**: An entry level system with relatively small capacity.
- **small**: An entry level system with relatively higher capacity than the very small system.
- **medium**: A higher capacity system than the small capacity system and with significantly more capabilities than the small systems.
- **large**: A system with very high capacity compared to the medium and small systems intended for large Enterprises.
- **mainframe**: A large system intended for Mainframe applications.

An NVSS Set Memory Access Classification storage product meeting the System Capacity attribute shall meet the qualitative description given.

5.12 Taxonomy Rules

A product shall satisfy all the attributes for its designated category and designated classification. If a product satisfies the attributes of multiple classifications, the product may be considered to be in any or all of these classifications. A product should be placed in the highest numerical classification that its features support.

A product shall be considered to be of a taxonomy category and classification if, in the Classification Table for the category (Table 4, Table 5, Table 6, Table 7, Table 8, and Table 9):

1. The product has each of the features and functionalities listed as **required** or described in a table entry;
2. The product has no feature or functionality listed as **prohibited or No;** and
3. The product satisfies the requirements of each of the attributes of the Classification.

A Classification entry of TBD is an entry which is not specified and therefore does not distinguish products; typically because there is not yet enough information to specify the entry.

The presence or absence of attributes labelled as Optional has no impact on the category and classification of a product.

The nature of features and functionalities listed as Not Specified or TBD is not material to the categorization of a product.
6 Capacity Optimization

6.1 Introduction

Hardware efficiencies are essential for reducing the amount of power used by storage, but equally real savings are obtained by capacity optimization. Capacity optimization refers to a set of techniques which collectively reduce the amount of storage necessary to meet storage objectives. Reduced use of storage (or increased utilization of raw storage) will result in less energy usage for a given task or objective.

Each of these techniques is known as a Capacity Optimization Method (COM). The COMs are largely, though not completely, independent. In other words, they provide benefit in any combination, though their combined effect does not precisely equal the sum of their individual impacts. Nonetheless, since data sets vary greatly, a hybrid approach using as many techniques as possible is more likely to minimize the capacity requirements of any given data set, and therefore is also likely to achieve the best results over the universe of data sets. In addition, the space savings achievable through the different COMs are sufficiently close to one another that they are roughly equivalent in storage capacity impact.

6.2 COMs Characterized

In this document, tests for the presence of the following COMs are defined:

- **Delta Snapshots**: applicable to backup, PIT copy availability and disaster recovery. Both read-only and writeable delta snapshots are featured in shipping systems, but there are fundamental technical differences between them, and some systems implement only the read-only version;

- **Thin Provisioning**: a technology that allocates the capacity as applications write data, rather than preallocating all the capacity at the time of provisioning;

- **Data Deduplication**: addresses issues caused by multiple backups of the same data sets, and the tendency of large data sets, due to human usage patterns, to contain many copies of the same data (not necessarily on file boundaries)\(^1\);

- **Compression**: takes advantage of the inherent compressibility of many data sets.

The following COMs and additional COMs may exist, however no test for presence is defined in this document.

- **Parity RAID**: addresses the need for disk-based redundancy.
7 Test Definition and Execution Rules

7.1 Overview

7.1.1 Execution Overview

This clause defines the data collection and testing methodology that shall be used in a SNIA Emerald™ Power Efficiency Measurement. The data collected using the procedures defined in this clause becomes the basis for the metrics defined in clause 8.

Disk Set Online Category, Disk Set Near Online Category, and NVSS Set Online Category products shall be tested as either block access or file access systems. RVML Set Removable Media Library Category and RVML Virtual Media Library Category products shall be tested as block access systems. Throughout this clause the block access execution rules are listed first followed by the file access execution rules.

Materials and information to support testing according to this document are available at the SNIA Emerald™ Program web site[13].

Table 10 is an informational guide to show the sub-clauses of this clause that apply to testing a product of a given Category.

a No test procedure is provided by this document.

7.1.2 Block Access Execution Overview
A SNIA Emerald™ Power Efficiency Measurement consists of a sequence of tests:
1. Pre-fill test, which puts data on the product under test;
2. Conditioning test, which assures accurate and reproducible measurements;
3. Active test, the basis for the active metrics;
4. Ready idle test, the basis of the ready idle metric;
5. Capacity optimization test (if defined), the basis of the secondary, capacity optimization metrics.

Some tests involve a timed sequence of defined measurements taken over defined intervals. Some tests have subordinate test phases. Clause 7 details the precise requirements for completing a given test for each taxonomy category, as well as any subordinate test phases defined within a given test. A valid measurement shall adhere to all requirements that are specific to the taxonomy category selected for the result (see subclause 7.2.2) as well as any general requirements for test execution (see subclause 7.2).

7.1.3 File Access Execution Overview
A SNIA Emerald™ Power Efficiency Measurement consists of a sequence of tests:
1. Execution of the four workloads, the basis for the active metrics;
Test Definition and Execution Rules

2. Ready idle test, the basis of the ready idle metric;
3. Capacity optimization test (if defined), the basis of the secondary, capacity optimization metrics.

7.2 General Requirements and Definitions

7.2.1 Configuration Guidelines

This document does not constrain the precise configuration and interconnection of the hardware necessary to complete a SNIA Emerald™ Power Efficiency Measurement. Figure 2 and Figure 3 are provided as guidelines, but test sponsors are free to modify their configuration to suit their particular needs and equipment, provided no other requirement of this document is violated.
Figure 2 – Sample Configuration Block Access

Figure 3 – Sample Configuration File Access
7.2.2 Product Under Test Configuration

The test sponsor shall identify one taxonomy set, category and classification for the product under test.

The product under test shall be configured to satisfy the requirements of the selected taxonomy set, category and classification.

The product under test shall represent a customer orderable configuration whose use within the selected one taxonomy set, category and classification is supported by the product vendor.

For a product under test in the RVML Set Removable Media Library Category, all drives shall provide the same stated maximum data rate.

7.2.3 RAS

RAS features can have a significant impact on the power consumption of the product under test. Typical RAS features are summarized in Table 11.

<table>
<thead>
<tr>
<th>Table 11 – Example RAS Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dual Controller (No SPOF Controller)</td>
</tr>
<tr>
<td>Mirroring (Local or remote, sync or async)</td>
</tr>
<tr>
<td>RAID 1, 4/5, 6</td>
</tr>
<tr>
<td>Snapshots (Full or Delta)</td>
</tr>
<tr>
<td>Disk Scrubbing</td>
</tr>
<tr>
<td>Multi-pathing</td>
</tr>
<tr>
<td>Disk Sparing</td>
</tr>
<tr>
<td>Dual Robotics</td>
</tr>
<tr>
<td>Drive-level Maintenance</td>
</tr>
<tr>
<td>Dual Power Supply</td>
</tr>
<tr>
<td>Variable-speed Fans</td>
</tr>
</tbody>
</table>

Any RAS features required to satisfy the requirements of the selected taxonomy set, category and classification shall be enabled. The choice of what additional RAS features to enable in a product under test is left to the test sponsor.

If the product under test includes RAS features that are enabled for any test or test phase, then they shall be enabled for all tests and test phase, unless disabling of RAS features is explicitly allowed in the definition of a given test or test phase.

7.2.4 Product Under Test Consistency

The physical and logical configuration of the product under test, including its configuration and tuning parameters, shall not be changed between or during a test or test phase unless explicitly allowed in the definition of the test or test phase.

7.2.5 No Non-Test Activity

Other than booting/starting the product under test and any test equipment employed during the test, no substantive work shall be performed on the product under test between the tests or test phases defined in this document, unless explicitly allowed in the definition of the test or test phase.
7.2.6 Test Sequence

All tests shall be executed as an uninterrupted sequence, except as explicitly allowed by the execution requirements defined for a given test or test phase.

7.2.7 Power

The power supplied to the product under test shall match one of the power profiles outlined in Table 12 or Table 13.

### Table 12 – Input Power Requirements (Products with Nameplate Rated Power ≤ 1500 W)

<table>
<thead>
<tr>
<th>Supply Voltage (AC RMS)</th>
<th>Phases</th>

<td>2 %</td>
</tr>
<tr>
<td>200 V, 208 V, 400 V</td>
<td>3</td>
<td>± 1 %</td>
<td>± 1 %</td>
<td>2 %</td>
</tr>
</tbody>
</table>

### Table 13 – Input Power Requirements (Products with Nameplate Rated Power > 1500 W)

<table>
<thead>
<tr>
<th>Supply Voltage (AC RMS)</th>
<th>Phases</th>
<th>Voltage Tolerance</th>
<th>Frequency Tolerance</th>
<th>Maximum Total Harmonic Distortion</th>
</tr>
</thead>
<tbody>
<tr>
<td>100 V, 115 V, 230 V</td>
<td>1</td>
<td>± 5 %</td>
<td>± 1 %</td>
<td>5 %</td>
</tr>
<tr>
<td>200 V, 208 V, 400 V</td>
<td>3</td>
<td>± 5 %</td>
<td>± 1 %</td>
<td>5 %</td>
</tr>
</tbody>
</table>

The power supplied to the product under test shall conform to the selected profile throughout test execution.

All batteries present in the product under test shall be fully charged at the start of testing.

7.2.8 Environmental

7.2.8.1 General Environmental Measurement Requirements

All measurements shall be conducted in a climate-controlled facility.

Note: The environmental conditions specified in subclauses 7.2.8.2 and 7.2.8.3 satisfy ASHRAE Class A1 standards for data centers as described in *Thermal Guidelines for Data Processing Environments*[^21][^22].

7.2.8.2 Temperature Requirements

Ambient temperature shall be within the range 18 °C to 28 °C for the duration of the test.

7.2.8.3 Humidity Requirements

Humidity shall be within the range 15 % relative humidity to 80 % relative humidity for the duration of the test.
Test Definition and Execution Rules

7.2.9 Power and Temperature Measurement Instrumentation

The solution under test shall include a recommended power meter (sometimes called an analyzer). If the selected power meter does not gather environmental data, the solution under test shall include an environmental meter. See Annex A for information regarding recommended meters.

The power meter shall be active throughout all tests and test phases and shall record:

- Input voltage to the product under test, to an accuracy within 2% at the 95% confidence level;
- Power consumption by the SUT, to the resolution summarized in Table 14.

The power and temperature measurements shall be recorded to durable media using a period of not more than 5 s and shall use a timestamp that is synchronized with the other components of the solution under test to a resolution of at least 1 s.

<table>
<thead>
<tr>
<th>Power Consumption (p)</th>
<th>Minimum Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p \leq 10 \text{ W} )</td>
<td>( \pm 10 \text{ mW} )</td>
</tr>
<tr>
<td>10 &lt; ( p \leq 100 \text{ W} )</td>
<td>( \pm 100 \text{ mW} )</td>
</tr>
<tr>
<td>( p &gt; 100 \text{ W} )</td>
<td>( \pm 1 \text{ W} )</td>
</tr>
</tbody>
</table>

The temperature, measured in degrees Celsius, to an accuracy of \( \pm 0.5 \) °C, as measured no more than 50 mm in front of (upwind of) the primary air inlet port for the product under test, shall be recorded to durable media using a reading rate of one reading every 10 s.

7.2.10 Workload Generator

7.2.10.1 Block Access Workload Generator

Vdbench (see Annex D) shall be used as the workload generator for Block Access testing. Information on access to Vdbench is provided in Annex D. Annex D identifies the version(s) of Vdbench that shall be used.

Test sponsors shall use a provided Vdbench Script (see Annex E). The script contains user adjustable parameters that the Test Sponsor may adjust within the constraints stated in the provided Vdbench Script.

This document takes precedence over any script if there is a conflict.

7.2.10.2 File Access Workload Generator

Test Sponsors shall use SPEC SFS® 2014\(^2\) (see Annex F) as the workload generator for file access testing. Information on access to SPEC SFS® 2014 is provided in Annex F. Annex F identifies the version(s) of SPEC SFS® 2014 that may be used.

Test sponsors shall use a provided File Access IO Load Driver Configuration File (see Annex G). A configuration file contains user adjustable parameters.

This document takes precedence over any script if there is a conflict.

\(^2\) SPEC SFS® is the trademark of a product supplied by the Standard Performance Evaluation Corporation. This information is given for the convenience of users of this document and does not constitute an endorsement by the SNIA of the product named. Equivalent products may be used if they can be shown to lead to the same results.
7.2.11 Instrumentation

7.2.11.1 Block Access Instrumentation
Vdbench shall be used as the workload generator and for collecting I/O rates and throughput data. The load generator shall be active throughout all tests and test phases of the active metrics and shall record:

- IO rate and throughput in IO/sec and MiB/s respectively, reported every minute.

7.2.11.2 File Access Instrumentation
SPEC SFS® 2014 (see Annex F) shall be used as the workload generator. An sFlow® (see Annex H) collector shall be used to collect storage performance data. sFlow® data shall be acquired by an sFlow® agent or agents located either in a network switch or the load generating host(s). The workload generator shall be active throughout all tests and test phases of the active metrics and shall record:

- The workload transition events in the log file for use during the data reduction process.

sFlow® agent(s) and an sFlow® collector shall be active and recording data throughout all tests and test phases of the active metrics and shall record:

- IO throughput in MiB/sec to/from product under test, reported every 10 seconds.

7.2.12 IO Profiles

7.2.12.1 Block Access IO Profiles

7.2.12.1.1 Overview
The particular IO stimuli used to drive the product under test during a test or test phase are specified in terms of an IO profile (a.k.a. workload) made up of multiple attributes:

- Name: the name of the IO pattern for this stimulus. The identifier for the associated test phase is included parenthetically, when appropriate;
- IO Size: the number of bytes requested by a given read or write operation;
- Read/Write Percentage: the mixture of read/write IO requests within an IO profile;
- Transfer Alignment: Minimum granularity of IO transfer addresses. All transfer addresses within an IO stream shall be a multiple of this value;
- Access Pattern: either one or the other of the following two alternatives:
  - Random: Randomly distributed throughout the address space of the product under test;
  - Sequential, as defined in subclause 4.2.36 sequential read and subclause 4.2.37 sequential write;

---

3 sFlow® is a trademark of InMon Corp. sFlow® is an industry standard technology for monitoring high speed switched networks. This information is given for the convenience of users of this document and does not constitute an endorsement by the SNIA of the product technology named. Equivalent products may be used if they can be shown to lead to the same results.
7.2.12.1.2 Sequential Access

The first IO within an IO Stream with a sequential access pattern shall use an offset randomly distributed throughout the address range provided to the workload generator, and rounded down to satisfy the Transfer Alignment requirement. Each subsequent IO request shall be sent to and satisfied by the product under test in sequence using an offset that satisfies Equation 7-1.

\[
O_{n+1} = \left( O_n + S \right) \ MOD \ R
\]

Where:
- \( O_n \) is an IO offset;
- \( S \) is the IO size;
- \( R \) is the formatted capacity of the product under test.

7.2.12.1.3 Hot Band IO Profile

7.2.12.1.3.1 Overview

The goal of the hot band IO profile is to provide a workload that considers the contribution of auto-tiering mechanisms, e.g., read caching. This workload consists of a mix of different IO sizes and access patterns with a skewed access across a range of blocks. For example, this skewed access tends to hold data in cache and creates “cache hits” for improved throughput and reduced power consumption.

7.2.12.1.3.2 Exponential Access Pattern

Within a hot band, the probability of block access is skewed. Not all blocks are accessed equally. For example, this can result in an access pattern that creates a cache-friendly workload. The larger the cache size, the better the cache hit rate, as shown in Figure 4.

\[
\text{Figure 4 – Percentage of Address Hit vs. Cache Size}
\]

7.2.12.1.3.3 Workloads within the Hot Band IO Profile

Table 15 shows information concerning workloads within the hot band IO profile.
Table 15 – Workloads within the Hot Band IO Profile

7.2.12.2 File Access IO Profiles

7.2.12.2.1 Overview of Workloads

The SPEC SFS® 2014 Benchmark is the workload generator used for all active tests. SPEC SFS® 2014 workloads are used to exercise the product under test during all active tests.

There are four workloads executed in the File Access sequence of tests. These are the VDA, Database, VDI and SW build workloads. The warmup interval of these workloads may be adjusted by the test sponsor to ensure stable operation throughout the measurement period.

For more information about the workloads, see the SPEC SFS® 2014 User’s Guide[4].

7.2.12.2.2 Video Data Acquisition (VDA) Workload

The workload generally simulates applications that store data acquired from a temporally volatile source (e.g., surveillance cameras). A stream refers to an instance of the application storing data from a single source (e.g., one video feed). The storage admin is concerned primarily about maintaining a minimum fixed bit rate per stream and secondarily about maintaining the fidelity of the stream. The goal of the storage admin is to provide as many simultaneous streams as possible while meeting the bit rate and fidelity constraints.

The business metric for the workload is STREAMS. The workload consists of two workload objects: VDA1 (data stream) and VDA2 (companion applications). Each stream corresponds to a roughly 36 Mb/s bit rate, which is in the upper range of high definition video.

7.2.12.2.3 Database (DATABASE) Workload

This workload represents the typical behavior of a database. The complete workload is a mixture of DB_TABLE and DB_LOG workloads. The DB_TABLE workload is the database component, and DB_LOG represents the log writer component of a database operation.
7.2.12.2.4 Virtual Desktop Infrastructure (VDI) Workload
This workload simulates a steady-state high-intensity knowledge worker in a VDI environment that uses full clones. This workload does not simulate a linked-clone environment. This is the behavior that was seen in traces between the hypervisor and storage when the VM’s were running on ESXi, Hyper-V, KVM and Xen environments.

7.2.12.2.5 Software Build (SW Build) Workload
The software build type workload is a classic meta-data intensive build workload. This workload was derived from analysis of software builds, and traces collected on systems in the software build arena. Conceptually, these tests are similar to running Unix ‘make’ against several tens of thousands of files. The file attributes are checked (metadata operations) and if necessary, the file is read, compiled, then data is written back out to storage.

7.2.13 IO Modes
All IO requests on a product under test shall be classified as either:
- Foreground IO, an externally-initiated, application-level request for data transfer between the load generator and the product under test, or;
- Background IO, a system-initiated request for data transfer within the product under test.

7.2.14 Average Response Time
The average response time for a test or test phase \( i \), \( RTA_i(T) \), is calculated over a specified time interval \( T \) in seconds.

7.2.15 Average Power
The average power for a test or test phase \( i \), \( PA_i(T) \), is the arithmetic average of sampled power measurements taken over a specified time interval \( T \) in seconds, as illustrated in Equation 7-2.

\[
PA_i(T) = \frac{\sum W_s}{n}
\]

Where:
- \( PA_i(T) \) is the average power during test or test phase \( i \), taken over a time interval of \( T \) seconds;
- \( W_s \) is power in watts measured at each sampling interval \( s \) taken during the time interval \( T \);
- \( n \) is the number of samples gathered by the power meter during the time interval \( T \).

7.2.16 Operations Rate
The operations rate for a test or test phase \( i \), \( O_i(T) \), is a measure of the average rate of completed work over a specified time interval \( T \). It is different for random workloads and sequential workloads.

For random workloads (i.e., random read, random write, and a mix of random read and random write), the operations rate is the average rate of IO operation completions during time interval \( T \).

For sequential workloads (i.e., sequential read or sequential write) and file access workloads, the operations rate is the average rate of data transfer in mebibytes per second (MiB/s) within time interval \( T \).

To provide a uniform basis for the metrics of a SNIA Emerald™ Power Efficiency Measurement, these two different measures of operations rate are both represented by \( O_i(T) \).
7.2.17 Periodic Power Efficiency

The periodic power efficiency for a test or test phase \( i \), \( EPP_i(T) \), is the ratio of operations rate over a specified time interval \( T \) and the average power during the same time interval \( T \) as illustrated by Equation 7-3.

\[
EPP_i(T) = \frac{O_i(T)}{PA_i(T)}
\]

Where:
- \( EPP_i(T) \) is the periodic power efficiency during test or test phase \( i \), taken over a time interval of \( T \) seconds;
- \( O_i(T) \) is the operations rate during test or test phase \( i \), taken over the same time interval of \( T \) seconds;
- \( PA_i(T) \) is the average power during test or test phase \( i \), taken over the same time interval of \( T \) seconds.

7.2.18 Measurement Interval

All tests and test phases state a minimum duration for their measurement interval. A measurement interval is a subset of a test or test phase during which the data underlying a specific metric or calculation is gathered.

A test sponsor shall ensure that a test’s metric is stable throughout the measurement interval by analyzing the test output as specified in subclause 7.2.19, and may extend some or all conditioning tests or test phases to achieve stability of that test’s metric.

7.2.19 Metric Stability Assessment

7.2.19.1 General

Metric M stability is assessed over the specified measurement interval defined in subclause 7.2.18, where M represents a selected performance/watt metric (e.g., periodic power efficiency \( EPP_i(T) \); see subclause 7.2.17. Particular test phases result in the generation of a continuous sequence of \( J \) fixed period samples of metric M values beginning after a specified warm-up period. The stability assessment evaluates a candidate sequence of \( K \) consecutive samples of metric M values where \( K \leq J \). The metric M sample period \( T \) is fixed by the test; hence the measurement interval is equal to \( K \times T \) (e.g., \( T = 60 \) seconds and \( K = 30 \) yielding a 30 min measurement interval producing 30 samples of metric \( EPP_i(60) \)). Each stability assessment shall supply a value for \( K \).

The stability of metric M is assessed by testing the flatness of the selected candidate sequence of K metric M values. It is recognized that this sequence, while otherwise flat, can have amplitude dispersal. Hence, the stability assessment is comprised of two tests:

1. A maximum allowed slope of a linear approximation of the K metric M values;
2. A smoothing function applied to the same K metric M values followed by comparison to a defined base reference value and a specified validity range.

The slope in (1) is determined from a least squares linear fit of the K metric M values.

The smoothing function in (2) consists of a weighted moving average \( S(M) \) of the same K metric M values. \( S(M) \) is based on a weighted average of present M and prior \( S(M) \) values.

The sequence of K metric M values shall meet the stability requirements of both tests to be considered stable.
7.2.19.2 Assessment Method

Assessing the stability of metric M values consists of the following test flow:

1. Select the first sample immediately after the warm-up period and set this point as N = 0. There shall be at least J = K metric M samples after this point;
2. Perform both the least squares linear fit test on the \((M_{N+1}..M_{N+K})\) sequence as described in 7.2.19.3 and the weighted moving average test on the same \((M_{N+1}..M_{N+K})\) sequence as described in 7.2.19.4;
3. If either test fails, N is incremented and start again at (2) above as long as incremented N + K ≤ J;
4. If full range J is exhausted without both tests passing, the metric M is deemed not stable;
5. If both tests pass, the metric M is deemed stable.

Once a stable sequence has been found, the assessment may continue looking for more stable sequences by continuing to increment N until incremented N + K = J.

7.2.19.3 Least Squares Linear Fit Test

The least squares linear fit test is performed over the K metric M values \((M_{N+1}..M_{N+K})\). The least squares linear fit calculation over this sequence returns a fitted line slope value and an intercept value as shown in Equation 7-4.

Equation 7-4: Least Squares Linear Fit Calculation

\[
Slope(M) = \frac{\sum_{n=1}^{K} M_{N+n}(12n - 6K - 6) / (K(K-1)(K+1))}{\sum_{n=1}^{K}-\}
\]

\[
Int(M) = \frac{\sum_{n=1}^{K} M_{N+n}}{K} - \frac{Slope(M)(K+1)}{2}
\]

\[Y = (n \cdot Slope(M)) + Int(M)\]

Where:
- \(\text{Slope(M)}\) is the slope of the least squares fit line;
- \(\text{Int(M)}\) is the intercept of the least squares fit line;
- \(M_{N+n}\) is the \(N+n\)-th sample value of metric M.

To be stable, the value \(Y\) in Equation 7-4 of the least squares fit line at sample point \(n = K\) shall not be more than 5 % different than the value \(Y\) in Equation 7-4 of the least squares fit line at sample point \(n = 1\).

7.2.19.4 Weighted Moving Average Test

The weighted moving average test is performed over the K metric M values \((M_{N+1}..M_{N+K})\), as defined in Equation 7-5.

Equation 7-5: Weighted Moving Average Calculation

\[
Base(M) = \frac{\sum_{n=1}^{K} M_{N+n}}{K}
\]

\[S_{n}(M) = wM_{N+n} + (1-w)S_{n-1}(M), \text{ for } n = 1..K\]

\[S_{0}(M) = Base(M)\]
Test Definition and Execution Rules

Where:
- Base(M) is the base reference value used to establish stability;
- \( M_{N+n} \) is the \( N+n \)-th sample value of metric \( M \);
- \( S_n(M) \) is the \( n \)-th value of the weighted moving average of metric \( M \);
- \( w \) is the factor that determines how much weight a new sample has in the moving average \( S_n(M) \) - each stability assessment shall supply a value for \( w \);
- \( S_0(M) \) is the initial value of the weighted moving average.

To be stable, each value of \( S_n(M) \) for \( n = 1..K \) shall not differ from base reference \( Base(M) \) by more than \( \pm 5 \% \).

7.3 Random Block Access Tests

7.3.1 Introduction

Subclause 7.3 applies to block access testing of Disk Set Online Category, Disk Set Near-Online Category, and NVSS Set Disk Access Category products.

7.3.2 Solution Under Test Configuration and Protocol Requirements

If a product under test is based on an industry standard storage protocol, the product under test shall adhere to all mandatory parts of the protocol specification.

All transport protocols used by load generator threads to access the product under test shall be disclosed. Transport protocols not involved in the test data flow may be disclosed.

7.3.3 Pre-fill Test

7.3.3.1 Overview

The pre-fill test is intended to provide a working data set on the storage system to be used with the other testing sets.

7.3.3.2 Procedure

- The product under test shall have a minimum of 50 \% of the formatted capacity pre-filled with the IO pattern described in Table 18 before continuing to the Conditioning Test;
- The data used to pre-fill the product under test shall be a 2:1 compression pattern, when compressed by gzip (see Annex J), using the latest version and compression algorithm level 6;
- Each IO stream shall issue each IO request synchronously, with each subsequent IO request issued immediately following the completion of its predecessor;
- The pre-fill test is defined to begin when the first request from the IO streams is issued by the load generator;
- IO transfer size and alignment is picked by the test sponsor;
- The pre-fill test shall last for at least the amount of time required to reach the pre-fill requirements of the product under test;
- The following test phases shall only access the space that was pre-filled.

<table>
<thead>
<tr>
<th>IO Profile</th>
<th>Read/Write Percentage</th>
<th>IO Intensity</th>
<th>Access Pattern</th>
<th>Data Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequential Write</td>
<td>0/100</td>
<td>100</td>
<td>Sequential</td>
<td>2:1 compression</td>
</tr>
</tbody>
</table>
7.3.4 Conditioning Test

7.3.4.1 Overview

The conditioning test is intended to provide a uniform initial condition for subsequent measurement(s) and to:

- Demonstrate the ability of the product under test to process IO requests;
- Ensure that each storage device in the product under test is fully operational and capable of satisfying all supported requests within the constraints of the taxonomy set, classification, and category identified for the product under test;
- Achieve typical operating temperature;
- Optionally, to provide a time period to allow the product under test to monitor/learn the characteristics of the workload and subsequent tiered storage data migration.

The limitations of timely test execution make it impossible to remove all variability between results, or to provide complete pre-testing stability. Test sponsors are encouraged to minimize the impact of certain long-duration or infrequent changes to the product under test that can impact test results, including:

- Cache stability;
- Maintenance cycles.

7.3.4.2 Conditioning Procedure

7.3.4.2.1 Procedure

The conditioning test shall begin when the first request from the IO streams is issued by the load generator.

Each IO stream shall issue each IO request synchronously, with each subsequent IO request issued immediately following the completion of its predecessor.

The load generator shall initiate a number of independent IO streams equal to or greater than the number of LUNS made available to the workload generator by the product under test.

Each IO stream shall issue a sequence of IO requests with the IO profile shown in Table 19.

<table>
<thead>
<tr>
<th>IO Profile</th>
<th>Read/Write Percentage</th>
<th>IO Intensity</th>
<th>Access Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hot band</td>
<td>See Table 15</td>
<td>100</td>
<td>See Table 15</td>
</tr>
</tbody>
</table>

If the product under test includes functionality that requires changes to the IO profile defined in Table 19 in order to meet the intent stated in subclause 7.3.4.1, the changes shall be disclosed.

The conditioning test shall last for a minimum of 12 h any part of which may be used for workload monitoring/learning of a tiered configuration.

7.3.4.2.2 Tiered Storage Configuration Data Migration Phase

If tiered storage is deployed, a migration phase may be included immediately following the monitoring/learning phase to allow data relocation into the appropriate tiers. If the migration phase is included, the IO intensity during the migration phase shall be at least 5 % per the IO profile defined in Table 19. If auto-tiering is deployed, it shall be disclosed.
7.3.4.3 Data to be Collected
During the conditioning test, the following data shall be collected at successive 1 min intervals:
- Average response time to complete an IO, $RTA_{sc}(60)$ (see subclause 7.2.14), reported to a precision of 1 ms.

7.3.4.4 Validity
The conditioning test shall satisfy the following conditions in order to be considered valid:
- All IOs issued shall complete successfully;
- During the final four hours of the conditioning test, $RTA_{sc}(14400)$ shall not exceed 20 ms. This requirement does not apply to Near-Online systems.

7.3.5 Block Access Active Test

7.3.5.1 Overview
The active test collects data for test phases defined in subclause 7.3.5.2.
The active test shall begin immediately following the conditioning test.

7.3.5.2 Test Phases
Table 20 defines the sequence of test phases, and their associated IO profiles, for this test.

<table>
<thead>
<tr>
<th>Table 20 – Online and Near-Online Testing: Active Test Phase IO Profiles</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IO Profile (Test Phase i)</strong></td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>1 Hot Band Workload (i=HB)</td>
</tr>
<tr>
<td>2 Random Write (i=RW)</td>
</tr>
<tr>
<td>3 Random Read (i=RR)</td>
</tr>
<tr>
<td>4 Sequential Write (i=SW)</td>
</tr>
<tr>
<td>5 Sequential Read (i=SR)</td>
</tr>
</tbody>
</table>

7.3.5.3 Procedure
The active test is composed of a set of test phases, which shall be executed as an uninterrupted sequence, in the order presented in Table 20.

Within the active test, each test phase shall begin when the first request from its IO streams is issued by the load generator.
Each test phase shall launch a test-sponsor-selected number of independent IO streams.
Each IO stream shall issue its IO requests synchronously, with each subsequent IO request issued immediately following the completion of its predecessor. All IO operations shall transfer data, either reading or writing. The IO stream does not include any idle or “think time.”
Each IO stream shall issue a sequence of IO requests matching the IO profile defined for the current test phase in Table 20.
Within the active test, each test phase shall last for a minimum of 40 min, comprised of a minimum 10 min warm-up period followed by a minimum 30 min measurement interval.
7.3.5.4 Data to be Collected
During a given test phase, the following data shall be collected at successive 1 min (T = 60 s) intervals:

- Average response time to complete an IO, RTA\(_i\)(60) (see subclause 7.2.14 reported to a precision of 1 ms;
- Average power, PA\(_i\)(60) (see subclause 7.2.15);
- Operations rate, O\(_i\)(60) (see subclause 7.2.16).

7.3.5.5 Validity
Each test phase execution shall satisfy the following conditions in order to be considered valid:

- The access pattern supplied by the load generator shall match the IO profile selected for the test phase from Table 20;
- All IOs issued in a test phase complete successfully;
- The EPP\(_i\)(60) (see subclause 7.2.17) shall be stable (see subclause 7.2.19) throughout the measurement interval (see subclause 7.2.18). The test sponsor may use any consecutive 30 min interval that is found to be stable as the measurement interval for the purposes of calculating the primary metric for that phase (see subclause 7.2.18). A value of 0,1 shall be used for the weighing factor w and a value of 30 shall be used for K in subclause 7.2.19;
- Each RTA\(_\text{HB}\)(60), RTA\(_\text{RW}\)(60), and RTA\(_\text{RR}\)(60) within the measurement interval, shall not exceed 80 ms. This requirement does not apply to Disk Set Near-Online Category systems;
- RTA\(_\text{HB}\)(1 800), RTA\(_\text{RW}\)(1 800) and RTA\(_\text{RR}\)(1 800), based on the measurement interval, shall not exceed 20 ms. This requirement does not apply to Disk Set Near-Online Category systems.

All COM functionality active during the capacity optimization test (see subclause 7.6) may be disabled at the discretion of the test sponsor during the active test.

7.4 File Access Tests

7.4.1 Introduction
Subclause 7.4 applies to file access testing of Disk Set Online Category, Disk Set Near-Online Category, and NVSS Set Disk Access Category products.

7.4.2 General
This document specifies how the SPEC SFS\textsuperscript{®} 2014 Benchmark is to be run as the workload generator for measuring and reporting storage power efficiency results. These rules have been adapted by the SNIA from the run rules for the SPEC SFS\textsuperscript{®} 2014 Benchmark as established by the SPEC. The rules are intended to ensure that results generated with this suite are meaningful, comparable to other generated results, and are repeatable.

The active tests are managed through the execution of the SfsManager script, using a File Access IO Load Driver Configuration File as input. Refer to the User Guide for the SNIA Emerald\textsuperscript{™} Power Efficiency Measurement Specification V3\textsuperscript{14} for details.

All loadpoints of a given workload shall be run as an uninterrupted sequence except that removal of files is allowed between workloads.

The product under test may be rebooted between workloads, but shall not be rebooted between loadpoints of a workload.
Each workload constitutes a test phase. Each workload produces 10 results, each for a different level of intensity. The test sponsor shall choose the most favorable of those results as the Measurement Interval to process and use for validation and calculation of the primary metric for that test phase.

7.4.3 Solution Under Test Configuration Requirements

7.4.3.1 Software Requirements

7.4.3.1.1 Solution Under Test Software

The solution under test shall have sufficient software installed to be able to access stable storage and writing of data to stable storage shall be enabled.

7.4.3.1.2 Workload Generator Source Code Changes

The SPEC SFS® 2014 Benchmark shall be used in an unmodified form as provided by SPEC, with the exception that errata patches and service packs for the SPEC SFS® 2014 Benchmark provided by the Storage Performance Evaluation Corporation[6] may be applied to the workload generator source code.

Note: By SPEC policy, these errata patches and service packs are performance-neutral.

7.4.3.2 Storage Solution Configuration and Protocol Requirements

7.4.3.2.1 Storage protocol requirements

If a product under test is based on an industry standard storage protocol, for example, NFS[11] or SMB[12], the product under test shall adhere to all mandatory parts of the protocol specification.

The workload generator automatically conducts a minimal functional validation test at the start of every test iteration, and will halt execution if the validation test fails.

All transport protocols used by load generator threads to access the product under test shall be disclosed. Transport protocols not involved in the test data flow may be disclosed.

7.4.3.2.2 Load Generator configuration requirements

The load generators in the solution under test shall be homogenous with respect to their operating system type, version, and patch level.

7.4.3.2.3 Stable Storage Requirements

Data written to the API and acknowledged as stable shall be in stable storage when acknowledged.

See Annex C for a full definition of stable storage.

7.4.3.3 Test Execution Requirements

7.4.3.3.1 General

This section details the requirements governing how the test is to be executed.

7.4.3.3.2 Valid methods for test execution

The test shall be executed by using the SfsManager on the prime client (see SPEC SFS® 2014 User’s Guide[4]).

7.4.3.3.3 File System Creation and Configuration

The components of the solution that hold the data and/or metadata for the file systems under test shall follow the stable storage requirements detailed in subclause 7.4.3.2.3.

The file systems of the product under test may be re-initialized between workloads.
Note: The load generator re-initialization of data between tests might have an initializing effect on the underlying storage, based on the design of the product under test.

7.4.3.3.4 Data Point Specification Requirements

The result of test execution is the set of data points for the product under test which are used to calculate the test metrics. The measurement of all data points shall be made within a single test execution run, starting with the lowest requested load level and proceeding to the highest requested load level.

Test results shall be based on at least 10 load points (excluding a business metric of zero). The load points should be as uniformly spaced as possible. Each load point shall be within 30% of its nominal uniformly-spaced value. The nominal interval spacing is the maximum requested load divided by the number of requested load points. This means the distance between zero and the first requested load point shall also fall within the nominal interval spacing. The product under test shall support a load of a business metric of at least 10.

Any invalid data points will invalidate the entire test. A data point is invalid if the workload generator reports it as invalid.

The following types of changes shall not be made to the solution under test during execution of the test or between data point collection:

- Manual change of the configuration of either the product under test or the testbed configuration;
- Reboots of the load generator or the product under test;
- File system initialization (e.g., “newfs/format”).

If any requested load level or data point is rerun for any reason, the entire test execution shall be restarted, i.e., the series of requested load levels repeated in whole.

7.4.3.3.5 SPEC SFS® 2014 Benchmark Modifiable Parameters

7.4.3.3.5.1 General

Each workload has a number of parameters which are configurable. These configuration parameters are set by using a File Access IO Load Driver Configuration File (see Annex G) on the prime client (see SPEC SFS® 2014 User’s Guide). Parameters outside of the set specified in subclause 7.4.3.3.5 shall not be modified.

Parameters which may be modified for test execution are indicated in subclause 7.4.3.3.5.

7.4.3.3.5.2 BENCHMARK

Name of the workload to run. Valid values are: DATABASE, SWBUILD, VDA, or VDI.

7.4.3.3.5.3 LOAD

Each workload has an associated business metric as a unit of workload. The magnitude of the workload to run is specified with the LOAD parameter in units of the workload’s business metric. Valid values for LOAD are either a starting number or a list of values, all positive integers. If a single value is specified, it is interpreted as a starting value and used in conjunction with INCR_LOAD and NUM_RUNS. The Table 21 shows the name for the business metric corresponding to each workload type.
If a list of values if specified, at least 10 uniformly spaced business metric load values shall be specified for valid test execution.

Note: Some rules of thumb for the resources required per business metric load unit for the different workloads:

Minimum storage capacity needed for product under test per business metric load unit:

<table>
<thead>
<tr>
<th>Workload</th>
<th>Business Metric (LOAD parameter)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE</td>
<td>DATABASES</td>
</tr>
<tr>
<td>SWBUILD</td>
<td>BUILDS</td>
</tr>
<tr>
<td>VDA</td>
<td>STREAMS</td>
</tr>
<tr>
<td>VDI</td>
<td>DESKTOPS</td>
</tr>
</tbody>
</table>

Minimum load generation RAM needed per business metric load unit:

<table>
<thead>
<tr>
<th>Workload</th>
<th>Load Generation RAM per LOAD increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE</td>
<td>55 MiB per LOAD increment</td>
</tr>
<tr>
<td>SWBUILD</td>
<td>400 MiB per LOAD increment</td>
</tr>
<tr>
<td>VDA</td>
<td>10 MiB per LOAD increment</td>
</tr>
<tr>
<td>VDI</td>
<td>8 MiB per LOAD increment</td>
</tr>
</tbody>
</table>

7.4.3.3.5.4 **INCR_LOAD**
Incremental increase in load for successive data points in a test run. This parameter is used only if LOAD consists of a single (initial) value. To ensure equally spaced points, the value of LOAD and INCR_LOAD shall be equal.

7.4.3.3.5.5 **NUM_RUNS**
The number of load points to run and measure (minimum of 10). This parameter is used only if INCR.Load is specified.

7.4.3.3.5.6 **CLIENT_MOUNTPOINTS**
The list of local mount points, local directories, or shares, to use in the testing. The value of CLIENT_MOUNTPOINTS can take several different forms:

- UNIX style: client:/exportfs1 client:/exportfs2 …:
  - Used for local storage or mounted network shares;
- Windows style: client:\server\exportfs1 client:\server\exportfs2 …;
- Use a file that contains the mount points: mountpoints_file.txt:
  - For examples of the format for this external file, see the *SPEC SFS® 2014 User’s Guide*[^4].

[^4]: SNIA Emerald™ Power Efficiency Measurement Specification V4.0.0
    SNIA Technical Position
The business metric values are spread among the client mount points in the following way. If the number of items \( N \) in the \( \text{CLIENT}_\text{MOUNTPOINTS} \) list is greater than the business metric value \( L \) (the current value for \( \text{LOAD} \)), then the first \( L \) items from the list are used, one business metric value per client/mountpoint. If \( L > N \), then the \( N + 1 \) business metric value will wrap around to the beginning of the list and allocation proceeds until all \( L \) business metrics have been allocated, wrapping around to the beginning of the list as many times as is necessary.

Reminder: If using a Windows-based load generator, the prime client (see \textit{SPEC SFS® 2014 User's Guide}) must not be listed in the \( \text{CLIENT}_\text{MOUNTPOINTS} \) list.

### 7.4.3.3.5.7 EXEC_PATH
The full path to the \textit{SPEC SFS® 2014} executable. Currently the executable is called netmist for POSIX systems and netmist_pro.exe for Windows systems. The same path will be used on all clients, so the executable must be at the same path on all clients.

### 7.4.3.3.5.8 USER
The user account name, which must be configured on all clients, to be used for the test execution. To specify a domain, prefix the user with the domain name, separated by a backslash, e.g., `DOMAIN\User33`

### 7.4.3.3.5.9 WARMUP_TIME
The amount of time, in seconds, that the test will spend in WARMUP before initiating the measurement ("RUN") phase. The minimum is 300 s (5 min). The maximum value is 604,800 s (7 d).

### 7.4.3.3.5.10 IPV6_ENABLE
Set to "1" or "Yes" when IPv6 will be used to communicate with other load generator processes.

### 7.4.3.3.5.11 NETMIST_LOGS
Set the path at which netmist will store client log files. The same path will be used on all clients. If this path is not set, `/tmp/` or `c:\tmp\` will be used.

### 7.4.3.3.5.12 PASSWORD
The password for the user specified in USER. (Only applicable when running on Windows platforms)

### 7.4.3.4 File Access Active Test Sequence and corresponding Business Metrics
Table 22 shows the business metrics for various workloads in the File Access Active Test Sequence.

<table>
<thead>
<tr>
<th>Workload</th>
<th>Business Metric (LOAD parameter)</th>
<th>Primary Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE</td>
<td>DATABASES</td>
<td>EP(_{DB})</td>
</tr>
<tr>
<td>SWBUILD</td>
<td>BUILDS</td>
<td>EP(_{SWB})</td>
</tr>
<tr>
<td>VDA</td>
<td>STREAMS</td>
<td>EP(_{VDA})</td>
</tr>
<tr>
<td>VDI</td>
<td>DESKTOPS</td>
<td>EP(_{VDI})</td>
</tr>
</tbody>
</table>

### 7.4.3.5 Data to be Collected
During a given test phase, the following data shall be collected at 10 s intervals:

- The average throughput, \( O_i(10) \), from the sFlow\(^\text{®} \) agent(s) in MiB/s;
- Average power, \( P_A(10) \) (see subclause 7.2.15).
7.4.3.6 Validity

Each test phase execution shall satisfy the following conditions in order to be considered valid:

- All IOs issued in a test phase complete successfully;
- The EPP[10] (see subclause 7.2.17) shall be stable (see subclause 7.2.19) throughout the measurement interval (see subclause 7.2.18). The test sponsor may use any consecutive 300 s interval that is found to be stable as the measurement interval for the purposes of calculating the primary metric for that phase (see subclause 7.2.18). A value of 0.1 shall be used for the weighing factor w and a value of 30 shall be used for K in subclause 7.2.19.

A COM function active during the capacity optimization test (see subclause 7.6) may be disabled at the discretion of the test sponsor during the active test.

7.5 Random Block Access and File Access Ready Idle Test

7.5.1 Introduction

Subclause 7.5 applies to block access testing of Disk Set Online Category, Disk Set Near-Online Category, and NVSS Set Disk Access Category products.

7.5.2 Overview

The ready idle test collects data for the ready idle metric. The ready idle test shall begin immediately following the active test.

7.5.3 Procedure

No foreground IO shall be initiated on the product under test during the ready idle test other than that required to satisfy the instrumentation requirements in subclause 7.2.9.

The test sponsor shall select a duration of at least two hours for the ready idle test. The test sponsor shall use the final two hours of the test as the measurement interval for the purposes of calculating the average power for the ready idle test primary metric (see subclause 8.4.1).

7.6 Random Block Access and File Access Capacity Optimization Test

7.6.1 Introduction

Subclause 7.6 applies to block access testing of Disk Set Online Category, Disk Set Near-Online Category, and NVSS Set Disk Access Category products.

7.6.2 Overview

This section defines qualitative heuristics for validating the existence and activation of COMs that are present on the product under test. Each heuristic is a simple pass/fail test, intended only to verify the presence and activation of a particular Capacity Optimization Method.

7.6.3 Testing Requirements

The heuristics assess the impact on free space to determine whether or not a COM is present and active. The assessments rely on:

- FS_{st}: free space at the start of a test;
- FS_{et}: free space at the end of a test;
- S_{ds}: size of a data set (see subclause 7.6.4);
• $I_{\text{com}}$ the impact of the COM on overall storage space utilization within the heuristic. The precise formulation of this value is defined by each heuristic.

For the purpose of the COM tests, free space, as reported by the product under test, shall be used.

Test sponsors shall select which of the heuristics they wish to execute. Only heuristics which are executed can be marked as passed (see subclause 8.7.1).

If test sponsors choose to execute a heuristic, they shall execute all of its steps in sequence. The testing of storage equipment may have minimal interruptions between heuristic COMs as needed to set up for each selected heuristic test. Configuration changes shall not be made between heuristic tests.

Storage device(s) shall not be added or removed, nor changed in state (taken on or offline, made a spare or incorporated, etc.) and RAID groups shall not be changed during any particular COM test. In the event of an automated disk failure and subsequent RAID rebuild at any time during a test, the test shall be restarted after the rebuild has completed and the failed disk has been replaced per manufacturers guidelines for installed and working systems.

Some of the following subclauses use the term “container” meaning a collection of logical blocks, e.g., a LUN or file system.

The COM tests shall be run using the same access method (block or file) as used for other tests.

For a block access test, this typically requires having the test host place a file system on product under test. The free space and other storage space measurements required by the COMs tests shall be made on the product under test and shall not be made on an externally placed file system.

### 7.6.4 Generating Data Sets

Most heuristics require the generation and use of specific data sets as part of their existence test. There are three different data set categories depending on the needs of the particular heuristic:

- Completely irreducible;
- Dedupable but not easily compressible;
- Compressible but not dedupable.

Note: The required exclusivity of compressible and dedupable data sets comes from situations where certain systems do not have the ability to individually disable other COMs features during a particular heuristic test.

Each data set is to be approximately 2 GB in size and shall be generated by the COM Test Data Set Generator (see Annex I). Each data set will be created in a directory named by the user located on the product under test. There are numerous files in each directory, and the order in which they are presented depends on the operating system where the program is run.

Table 23 lists the data sets; these can be represented by a single file or by a directory (folder).
Test Definition and Execution Rules

Table 23 – Data Sets

<table>

7.6.5 Delta Snapshot Heuristics

7.6.5.1 General
Delta snapshots in a storage system can be detected using a straightforward algorithm:
1. Query the free space before taking a snapshot;
2. Attempt to create a snapshot;
3. In the case of a writeable snapshot, write something to the snapshot;
4. Query the free space after that snapshot to determine whether significant storage space has been used.

Note: Read-only and writeable delta snapshots are treated separately so that systems that only do read-only snapshots get credit for them.

7.6.5.2 Heuristic 1: Read-only delta snapshots
The method varies according to where the product under test places snapshots. Follow steps 1 or 2, and then proceed to step 3:
1. For a product under test that places snapshots in separate containers:
   a. On the product under test, create two containers, each 15 GB, with a tolerance of ± 10 %, in size. The amount of actual physical storage that is committed as a result of creating the containers will vary by product under test, and should be determined by the test sponsor in trials before a formal run of the test;
   b. Mount the first container on a host, via any chosen protocol;
   c. Determine the amount of free space $FS_{tot}$ available on the product under test as seen by the product under test;
   d. Using the COM Test Data Set Generator, write the irreducible data set to the first container;
   e. Perform a read-only delta snapshot of the first container and expose it through the second container, disabling any background copying mechanism. As an example, the snapshot of lun1 may be exposed as lun2;
   f. Perform whatever steps are necessary to mount the second container as a file system. Open a small file on this file system (i.e., one of the files in the irreducible data set), read some data from it, and close the file. Confirm that the file has been successfully read;
2. For a product under test that places snapshots on the originating container:
   a. On the product under test, create a container of 15 GB, with a tolerance of ± 10 %, in size.
      The amount of actual physical storage that is committed as a result of creating the container
      will vary by product under test, and should have been determined by the test sponsor in trials
      before a formal run of the test;
   b. Mount the container on the host via any chosen protocol;
   c. Determine the amount of free space $FS_{sot}$ available on the container as seen by the product
      under test;
   d. Using the COM Test Data Set Generator, write the irreducible data set to the container;
   e. Perform a read-only snapshot of the container, disabling any optional background copying
      mechanism;
   f. Perform whatever steps are necessary to mount the container as a file system. Open a file in
      the snapshot, read some data from it, and close the file. Confirm that the file portion has been
      successfully read;

3. Determine the amount of free space, $FS_{eot}$, available on the container containing the snapshot as
   seen by the product under test. Calculate the space required for the snapshot $I_{com} = FS_{sot} - FS_{eot}$.
   If $I_{com}$ is less than 2.5 GB, then the product under test shall be considered to have passed the test.

7.6.5.3 Heuristic 2: Writeable delta snapshots

This method varies according to where the product under test places snapshots. Follow steps 1 or 2, and then proceed to step 3:

1. For a product under test that places snapshots in separate containers:
   a. On the product under test, create two containers, each 15 GB, with a tolerance of ± 10 %, in size.
      The amount of actual physical storage that is committed as a result of creating the containers
      will vary by product under test, and should have been determined by the test sponsor in trials
      before a formal run of the test;
   b. Mount the first container on a host, via any chosen protocol;
   c. Determine the amount of free space $FS_{sot}$ available on the product under test as seen by the
      product under test;
   d. Using the COM Test Data Set Generator, write the irreducible data set to the first container;
   e. Perform a writeable snapshot of the first container and expose it through the second
      container, disabling any optional background copying mechanism. As an example, the
      snapshot of lun1 may be exposed as lun2;
   f. Perform whatever steps are necessary to mount the second container as a file system. Open
      a small file on this file system (i.e., one of the files in the irreducible data set), write a few
      characters to it, and close the file. Confirm that the file has been successfully written with its
      new contents;

2. For an product under test that places snapshots on the originating container:
   a. On the product under test, create a container of 15 GB, with a tolerance of ± 10 %, in size.
      The amount of actual physical storage that is committed as a result of creating the container
      will vary by product under test, and should have been determined by the test sponsor in trials
      before a formal run of the test;
   b. Mount the container on the host via any chosen protocol;
   c. Determine the amount of free space $FS_{sot}$ available on the container as seen by the product
      under test;
   d. Using the COM Test Data Set Generator, write the irreducible data set to the container;
e. Perform a writeable snapshot of the container, disabling any optional background copying mechanism;
f. Perform whatever steps are necessary to mount the container as a file system. Open a small file in the snapshot (i.e., one of the files in the irreducible data set), write a few characters to it, and close the file. Confirm that the file has been successfully written;

3. Determine the amount of free space $FS_{sot}$ available on the container containing the snapshot as seen by the product under test. Calculate the space required for the snapshot $I_{com} = FS_{sot} - FS_{sot}$. If $I_{com}$ is less than 2.5 GB and the small file was successfully written onto the writeable delta snapshot destination, then the product under test shall be considered to support writable delta snapshots.

7.6.5.4 Thin Provisioning Heuristics

7.6.5.4.1 General

The goal of this heuristic is not to highlight differences of thin provisioning implementations between vendors; it is to be used simply to ensure that the product under test does have some sort of thin provisioning capability.

7.6.5.4.2 Thin Provisioning Heuristics – Block Access Test

A test sponsor seeking credit for thin provisioning shall:

1. Establish the total usable space or establish a pool of usable space as seen by the product under test;
2. Enable thin provisioning if not already enabled;
3. Request allocation of $N$ LUNs of formatted capacity $M$ such that $N \cdot M$ is at least 20 % greater than the total (or pooled) formatted capacity. This shall result in an allocation of all requested LUNs.

The product under test shall be considered to support thin provisioning if step 3 is successful.

7.6.5.4.3 Thin Provisioning Heuristics – File Access Test

A test sponsor seeking credit for thin provisioning shall:

1. Establish the total usable space or establish a pool of usable space as seen by the product under test;
2. Enable thin provisioning if not already enabled;
3. Create $N$ file systems of formatted capacity $M$ such that $N \cdot M$ is at least 20 % greater than the total free space.

The product under test shall be considered to support thin provisioning if step 3 is successful.

7.6.5.5 Data Deduplication Heuristics

A test sponsor seeking credit for data deduplication shall:

1. On the product under test, create a container large enough in size to engage the product under test data deduplication mechanism. The amount of actual physical storage that is committed as a result of creating the container will vary by product under test, and should have been determined by the test sponsor in trials before a formal run of the test;
2. Perform whatever steps are necessary to make the container visible on the host from which tests are being run, and create and mount a local file system on that container;
3. Determine the amount of free space $FS_{sot}$ available on the container as seen by the product under test;
4. For cases in which the 2 GB dedupable data set is sufficient, write the 2 GB dedupable data set to the container;

5. For cases in which a larger data set is required:
   a. Establish the necessary data set size in 2 GB increments;
   b. Using the COM Test Data Set Generator, write the 2 GB dedupable data set to the container;
   c. In the same container, write as many (N) 2 GB irreducible data sets as are required to meet system requirements for data deduplication. For each:
      1. Create a new directory for each data set;
      2. Invoke the COM Test Data Set Generator tool on each directory with the same “salt” value each time;

6. Wait a suitable amount of time as specified by the test sponsor for any non-inline data deduplication processes to have completed;

7. Determine the amount of free space $FS_{sot}$ available on the container as seen by the product under test;

8. Calculate the fraction of formatted capacity saved by data deduplication $I_{com} = (1 - ((FS_{sot} - FS_{eot}) / ((N+1) \cdot S_{ds}))$ where $S_{ds}$ is the size of the single dedupable data set.

If $I_{com}$ is greater than 0.1 then the product under test shall be considered to support data deduplication.

Note: Data set size is not necessarily important for the purposes of data deduplication detection. However, larger data sets may be necessary to activate existing data deduplication functionality. This heuristic allows the building of a larger data set, consisting of a single 2 GB dedupable data set and the option of a test sponsor-determined integer number of 2 GB irreducible data sets, collectively used to demonstrate data deduplication capability. The addition of identical 2 GB irreducible data sets can themselves be dedupable so it is a requirement to generate each with the same “salt” value.

7.6.5.6 Compression Heuristics

Data set size might be important for the purposes of compression detection. However, larger data sets might be necessary to activate existing compression functionality. This heuristic allows the building of a larger data set, consisting of a single 2 GB compressible data set and the option of a test sponsor-determined integer number of 2 GB compressible data sets, collectively used to demonstrate compression capability. The addition of identical 2 GB compressible data sets can themselves be dedupable, therefore it is a requirement to generate each with a different “salt” value.

A test sponsor seeking credit for compression of primary storage shall:

1. On the product under test, create a container large enough in size to engage the product under test compression mechanism. The amount of actual physical storage that is committed as a result of creating the container will vary by product under test, and should have been determined by the test sponsor in trials before a formal run of the test;

2. Perform whatever steps are necessary to make the container visible on the host from which tests are being run, and create and mount a local file system on that container;

3. Determine the amount of free space $FS_{sot}$ available on the container as seen by the product under test;

4. For cases in which the 2 GB compressible data set is sufficient:
   a. Using the COM Test Data Set Generator, write the 2 GB compressible data set to the container;

5. For cases in which a larger data set is required:
   a. Establish the necessary data set size in 2 GB increments;
Test Definition and Execution Rules

b. Using the COM Test Data Set Generator, write the 2 GB compressible data set to the container;

c. In the same container, write as many additional \((N)\) 2 GB compressible data sets as are required to meet system requirements. For each:
   1. Create a new directory for each data set;
   2. Invoke the COM Test Data Set Generator tool on each directory with a unique “salt” value each time;

6. Wait a suitable amount of time as specified by the test sponsor for any non-inline compression processes to have completed;

7. Determine the amount of free space \(FS_{eot}\) available on the container as seen by the product under test;

8. Calculate the fraction of formatted capacity saved by compression \(I_{com} = (1 - ((FS_{eot} - FS_{eot}) / (N+1) \cdot Sds))\) where \(Sds\) is the size of the single compressible data set.

If \(I_{com}\) is greater than 0,1 then the product under test shall be considered to support compression.

7.7 RVML Set Removable Media Library Category Testing

7.7.1 Product Under Test Configuration Requirements

7.7.1.1 Introduction

Removable media library testing has additional configuration requirements.

7.7.1.2 Drive Counts

For removable media testing the product under test shall be configured to the requirements listed in Table 24. This table lists the number of tape/optical drives that shall be used during the Emerald testing. The drive counts are not allowed to change during the tests.

<table>
<thead>
<tr>
<th>Category</th>
<th>Drive Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Removable-2</td>
<td>Maximum Supported</td>
</tr>
<tr>
<td>Removable-3</td>
<td>Maximum Supported</td>
</tr>
<tr>
<td>Removable-5</td>
<td>25</td>
</tr>
<tr>
<td>Removable-6</td>
<td>25</td>
</tr>
</tbody>
</table>

7.7.1.3 Drive-level Compression

If the product under test supports drive-level compression, it shall be disabled throughout the tests.

7.7.1.4 Tape Robotics

If the product under test contains robotics, they shall be enabled and ready to process a tape/optical manipulation commands throughout the tests.

7.7.2 Pre-fill Test

There are no pre-fill requirements for removable media library testing.
7.7.3 Conditioning Test

7.7.3.1 Overview

The conditioning test is intended to provide a uniform initial condition for subsequent measurement(s) and to:

- Demonstrate the ability of the product under test to process IO requests;
- Ensure that each storage device in the product under test is fully operational and capable of satisfying all supported requests within the constraints of the taxonomy set, category, and classification identified for the product under test;
- Achieve typical operating temperature.

The limitations of timely test execution make it impossible to remove all variability between results, or to provide complete pre-testing stability. Test sponsors are encouraged to minimize the impact of certain long-duration or infrequent changes to the product under test that can impact test results, including:

- Cache stability;
- Maintenance cycles.

7.7.3.2 Procedure

The conditioning test shall begin when the first request from the IO streams is issued by the load generator.

Each IO stream shall issue each IO request synchronously, with each subsequent IO request issued immediately following the completion of its predecessor. The workload generator shall uniformly distribute the required IO requests among the IO streams, such that the maximum number of IO requests serviced by an IO stream is no more than 10% greater than minimum number of IO requests serviced by an IO stream.

The test sponsor shall ensure that all tape/optical drives are accessed during the conditioning test.

The workload generator shall initiate a number of independent IO streams equal to or greater than the number of tape/optical drives made available to the load generator by the product under test.

The test sponsor shall ensure that all tape/optical drives are:

- Loaded prior to the conditioning test;
- Rewound between the two phases of the conditioning test;
- Rewound at the end of the conditioning test.

The conditioning test shall consist of two phases, each lasting for a minimum of seven minutes shown in Table 25.

![Table 25](#)

### Table 25 – Removable Media Library Testing: Conditioning Test IO Profiles

<table>
<thead>
<tr>
<th>IO Profile</th>
<th>IO Size (KiB)</th>
<th>Read/Write Percentage</th>
<th>IO Intensity</th>
<th>Transfer Alignment (KiB)</th>
<th>Access Pattern</th>
</tr>
</thead>
<tbody>
<tr>

<td>256</td>
<td>0/100</td>
<td>100</td>
<td>256</td>
<td>Sequential</td>
</tr>
<tr>
<td>Sequential Read (i=C2)</td>
<td>256</td>
<td>100/0</td>
<td>100</td>
<td>256</td>
<td>Sequential</td>
</tr>
</tbody>
</table>

Each IO stream shall issue a sequence of IO requests satisfying the Sequential Write IO profile shown in Table 25 during the first phase of the conditioning test, and the Sequential Read IO profile shown in Table 25 during the second phase of the conditioning test.
If the product under test includes functionality that requires changes to the IO profile defined in Table 25 in order to meet the intent stated in subclause 7.7.3.1, the changes shall be disclosed.

**7.7.3.3 Data to be Collected**

During the conditioning test, the following data shall be collected at successive 1 min intervals:

- Average data rate reported for each drive, reported in MiB/s;
- Average power, \( PA_{(60)} \) (see 7.2.15);
- Operations rate, \( O_{(60)} \) (see 7.2.16).

**7.7.3.4 Validity**

The conditioning test shall satisfy the following conditions in order to be considered valid:

- All IOs issued shall complete successfully;
- The overall data rate for each drive present in the product under test for a given test phase shall be greater than or equal to 80 % of the maximum published data rate for that drive type.

**7.7.4 Active Test**

**7.7.4.1 Overview**

The active test collects data for the test phases defined below and is used to generate the power efficiency metrics.

The active test shall begin immediately following the conditioning test.

**7.7.4.2 Test Phases**

The active test is composed of two test phases, which shall be executed as an uninterrupted sequence, and separated by a rewind to Beginning of Tape (BOT), in the order presented in Table 26.

<table>
<thead>
<tr>
<th>IO Profile (Test Phase i)</th>
<th>IO Size (KiB)</th>
<th>Read/Write Percentage</th>
<th>IO Intensity</th>
<th>Transfer Alignment (KiB)</th>
<th>Access Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequential Write (i=SW)</td>
<td>256</td>
<td>0/100</td>
<td>100</td>
<td>256</td>
<td>Sequential</td>
</tr>
<tr>
<td>Sequential Read (i=SR)</td>
<td>256</td>
<td>100/0</td>
<td>100</td>
<td>256</td>
<td>Sequential</td>
</tr>
</tbody>
</table>

Table 26 defines the sequence of test phases, and their associated IO profiles, used during this test.

**7.7.4.3 Procedure**

Within the active test, each test phase shall begin when the first requested IO is issued by the load generator.

Each IO stream shall issue a sequence of IO requests matching the profile defined for the current test phase in Table 26.

Each test phase shall launch a number of independent IO streams equal to the number of drives present in the product under test. All drives in the product under test shall be capable of processing IO requests at the start of a test phase.
Each IO stream shall issue its IO requests synchronously, with each subsequent IO request issued immediately following the completion of its predecessor. All IO operations transfer data, either reading or writing. The IO stream does not include any idle or “think time.”

The first IO within a sequential IO Stream shall occur at Beginning of Tape (BOT). Each subsequent IO request shall be sent to and satisfied by the product under test in sequence using a transfer offset that satisfies Equation 7-6.

**Equation 7-6: Sequential Transfer Offset**

\[
O_{n+1} = (O_n + S) \mod R
\]

Where:
- \(O_n\) is an IO offset;
- \(S\) is the IO size;
- \(R\) is the formatted capacity of the product under test.

The workload generator shall uniformly distribute the required IO requests among the IO streams, such that the maximum number of IO requests serviced by an IO stream is no more than 10% greater than minimum number of IO requests serviced by an IO stream.

The test sponsor shall ensure that all tape drives are accessed throughout the active test.

**7.7.4.4 Data to be Collected**

During a given test phase, the following data shall be collected at successive 1 min (\(T = 60\) s) intervals:

- Average data rate reported for each drive, reported in MiB/s;
- Average power, \(PA_i(60)\) (see subclause 7.2.15);
- Operations rate, \(O_i(60)\) (see subclause 7.2.16).

**7.7.4.5 Validity**

Each test phase execution shall satisfy the following conditions in order to be considered valid:

- All IOs issued in a test phase complete successfully;
- The access pattern supplied by the workload generator shall match the IO profile selected for the test phase from Table 26;
- The EPP\(_i(60)\) shall be stable (see subclauses 7.2.17 and 7.2.19), based on the 1 min data collected according to subclause 7.7.4.4, throughout the measurement interval;
- The EPP\(_i(60)\) (see subclause 7.2.17) shall be stable (see subclause 7.2.19) throughout the measurement interval (see subclause 7.2.18). The test sponsor may use any consecutive 30-minute interval that is found to be stable as the measurement interval for the purposes of calculating the primary metric for that phase (see subclause 7.2.18). A value of 0,1 shall be used for the weighing factor \(w\) and a value of 30 shall be used for \(K\) in subclause 7.2.19;
- Each \(O_{SW}(1\,800)\) and \(O_{SR}(1\,800)\) rate for each drive present in the product under test for a given test phase shall be greater than or equal to 80% of the maximum published data rate for that drive type.

**7.7.5 Ready Idle Test**

**7.7.5.1 Overview**

The ready idle test collects data for the ready idle metric
The ready idle test shall begin immediately following the active test.

### 7.7.5.2 Procedure

No foreground IO shall be initiated on the product under test during the ready idle test other than that required to satisfy the instrumentation requirements in subclause 7.2.9.

The ready idle test shall begin after any loaded storage devices have been unloaded from the tape drives and any robotics activity has completed.

The test sponsor shall select a duration of at least two hours for the ready idle test. The test sponsor shall use the final two hours of the test as the measurement interval for the purposes of calculating the average power for the ready idle test primary metric (see subclause 8.5.1).

### 7.7.6 Capacity Optimization Test

This document does not define a Capacity Optimization Method test for the Removable Media Library taxonomy category.

### 7.8 RVML Set Virtual Media Library Category Testing

#### 7.8.1 Pre-fill

There are no pre-fill requirements for virtual media library testing.

#### 7.8.2 Conditioning Test

##### 7.8.2.1 Overview

The conditioning test is intended to provide a uniform initial condition for subsequent measurement(s) and to:

- Demonstrate the ability of the solution under test to process IO requests;
- Ensure that each storage device in the product under test is fully operational and capable of satisfying all supported requests within the constraints of the taxonomy classification identified for the product under test;
- Achieve typical operating temperature.

The limitations of timely test execution make it impossible to remove all variability between results, or to provide complete pre-testing stability test sponsors are encouraged to minimize the impact of certain long-duration or infrequent changes to the product under test that can impact test results, including:

- Cache stability;
- Maintenance cycles.

##### 7.8.2.2 Procedure

The conditioning test shall begin when the first requested IO is issued by the load generator.

Each IO stream shall issue each IO request synchronously, with each subsequent IO request issued immediately following the completion of its predecessor.

The workload generator shall uniformly distribute the required IO requests among the IO streams, such that the maximum number of IO requests serviced by an IO stream is no more than 10% greater than minimum number of IO requests serviced by an IO stream.

The test sponsor shall ensure that all storage devices are accessed at some time during the conditioning test.
The workload generator shall initiate a number of independent IO streams equal to or greater than the number of virtual drives made available to the load generator by the product under test.

The test sponsor shall ensure that all virtual drives are:

- Loaded prior to the conditioning test;
- Rewound between the two phases of the conditioning test;
- Rewound at the end of the conditioning test.

The conditioning test shall consist of two phases, as shown in Table 27, each lasting for a minimum of seven minutes.

<table>
<thead>
<tr>
<th>Table 27 – Virtual Media Library Testing: Conditioning Test IO Profiles</th>
</tr>
</thead>
<tbody>
<tr>
<td>IO Profile</td>
</tr>
<tr>
<td>Sequential Write (i=C1)</td>
</tr>
<tr>
<td>Sequential Read (i=C2)</td>
</tr>
</tbody>
</table>

Each IO stream shall issue a sequence of IO requests satisfying the Sequential Write IO profile shown in Table 27 during the first phase of the conditioning test, and the Sequential Read IO profile shown in Table 27 during the second phase of the conditioning test.

If the product under test includes functionality that requires changes to the IO profile defined in Table 27 in order to meet the intent stated in subclause 7.8.2.1, the changes shall be disclosed.

7.8.2.3 Data to be Collected

During the conditioning test, the following data shall be collected at successive 1-minute intervals:

- Average data rate reported for each drive, reported in MiB/s;
- Average power, PA_i(60) (see subclause 7.2.15);
- Operations rate, O_i(60) (see subclause 7.2.16).

7.8.2.4 Validity

The conditioning test shall satisfy the following conditions in order to be considered valid:

- All IOs issued shall complete successfully;
- The overall data rate for each drive present in the product under test for a given test phase shall be greater than or equal to 90% of the maximum published native (without compression) data rate for that drive type.

7.8.3 Active Test

7.8.3.1 Overview

The active test collects data for the test phases defined below and is used to generate the power efficiency metrics.

The active test shall begin immediately following the conditioning test.
7.8.3.2 Test Phases

The active test is composed of a set of test phases, which shall be executed as an uninterrupted sequence, separated by a rewind to Beginning of Tape (BOT), in the order presented in Table 28.

Table 28 – Virtual Media Library Testing: Active Test Phase IO Profiles

<table>

Table 28 defines the sequence of test phases, and their associated IO profile for this test.

7.8.3.3 Procedure

Within the active test, each test phase shall begin when the first request from its IO streams is issued by the load generator. During the active test, the product under test shall include a number of virtual drives that is sufficient to reach 90 % of maximum published data rate for the drive type being emulated. There shall be no change to the number of virtual drives in the product under test between the sequential write and sequential read test phases.

Each test phase shall launch a number of independent IO streams equal to the number of virtual drives present in the product under test. All virtual drives in the product under test shall be capable of processing IO requests prior to the start of a test phase.

Each IO stream shall issue its IO requests synchronously, with each subsequent IO request issued immediately following the completion of its predecessor. All IO operations shall transfer data, either reading or writing. The IO stream does not include any idle or “think time.”

The first IO within an IO Stream shall use occur at Beginning of Tape (BOT). Each subsequent IO request shall be sent to and satisfied by the product under test in sequence using a transfer offset that satisfies Equation 7-7.

**Equation 7-7: Sequential Transfer Offset**

\[ O_{n+1} = (O_n + S) \mod R \]

Where:
- \( O_n \) is an IO offset;
- \( S \) is the IO size;
- \( R \) is the formatted capacity of the product under test.

The workload generator shall uniformly distribute the required IO requests among the IO streams, such that the maximum number of IO requests serviced by an IO stream is no more than 10 % greater than minimum number of IO requests serviced by an IO stream.

The test sponsor shall ensure that all storage devices that comprise the formatted capacity are accessed at some time during the active test.

If the product under test supports drive-level compression, it shall be disabled throughout the active test.

7.8.3.4 Data to be Collected

During a given test phase, the following data shall be collected at successive 1 min (T = 60 s) intervals:

- Average data rate reported for each virtual drive in the product under test, reported in MiB/s;
• Average power, PA_{i}(60) (see subclause 7.2.15);
• Operations rate, O_{i}(60) (see subclause 7.2.16).

7.8.3.5 Validity
Each test phase execution shall satisfy the following conditions in order to be considered valid:

• All IOs issued in a test phase complete successfully;
• The access pattern supplied by the workload generator shall match the IO profile selected for the test phase from Table 28;
• The EPP_{i}(60) (see subclause 7.2.17) shall be stable (see subclause 7.2.19) throughout the measurement interval (see subclause 7.2.18). The test sponsor may use any consecutive 30 min interval that is found to be stable as the measurement interval for the purposes of calculating the primary metric for that phase (see subclause 7.2.18). A value of 0.1 shall be used for the weighing factor w and a value of 30 shall be used for K in subclause 7.2.19;
• Each O_{SW}(1 800) and O_{SR}(1 800) rate for each drive present in the product under test for a given test phase shall be greater than or equal to 90 % of the maximum published data rate for that drive type.

7.8.4 Ready Idle Test

7.8.4.1 Overview
The ready idle test collects data for the ready idle metric.

The ready idle test shall begin immediately following the active test.

7.8.4.2 Procedure
No foreground IO shall be initiated on the product under test during the ready idle test other than that required to satisfy the instrumentation requirements in subclause 7.2.9.

The test sponsor shall select a duration of at least two hours for the ready idle test. The test sponsor shall use the final two hours of the test as the measurement interval for the purposes of calculating the average power.

7.8.5 Capacity Optimization Test
This document does not define a Capacity Optimization Method test for the RVML Set Virtual Media Library taxonomy category.
8 Metrics

8.1 Taxonomy Considerations
This document defines metrics for the Disk Set Online, Disk Set Near-Online, RVML Set Removable Media Library, RVML Virtual Media Library, NVSS Set Disk Access taxonomy categories.

8.2 Block Access Primary Metrics
This document defines the following primary metrics:

- Power efficiency for each test phase for Disk Set Online, Disk Set Near-Online, and NVSS Set Disk Access taxonomy category systems (see subclause 8.4):
  - EP_{HB} for Hot band (IO/s/W);
  - EP_{RR} for Random Read (IO/s/W);
  - EP_{RW} for Random Write (IO/s/W);
  - EP_{SR} for Sequential Read (MiB/s/W);
  - EP_{SW} for Sequential Write (MiB/s/W);
  - EP_{RI} for Ready Idle (GB/W).

- Power efficiency for each test phase for RVML Set Removable Media Library category systems (see subclause 8.5):
  - EP_{SW} for Sequential Write (MiB/s/W);
  - EP_{SR} for Sequential Read (MiB/s/W);
  - EP_{RI} for Ready Idle (GB/W).

- Power efficiency for each test phase for RVML Set Virtual Media Library category systems (see subclause 8.6):
  - EP_{SW} for Sequential Write (MiB/s/W);
  - EP_{SR} for Sequential Read (MiB/s/W);
  - EP_{RI} for Ready Idle (GB/W).

8.3 File Access Primary Metrics
This document defines the following primary metrics:

- Power efficiency for each test phase for Disk Set Online, Disk Set Near-Online, and NVSS Set Disk Access taxonomy category systems (see subclause 8.4) is:
  - EP_{VDA} for Video Data Acquisition (MiB/s/W);
  - EP_{DB} for Database (MiB/s/W);
  - EP_{VDI} for Virtual Desktop Integration (MiB/s/W);
  - EP_{SWB} for Software Build (MiB/s/W);
  - EP_{RI} for Ready Idle (GB/W).
8.4 Power Efficiency Metric for Random Block Access and File Access Systems

8.4.1 Ready Idle Test

For the ready idle test, the power efficiency metric represents the amount of raw capacity supported per watt of power required by the product under test. It is calculated as shown in Equation 8-1, as the ratio of:

- The raw capacity of the product under test, measured in GB;
- The average power, from the ready idle test, measured in watts.

\[
EP_{RI} = \frac{C_R}{PA_{RI}(7 200)}
\]

Where:
- \(EP_{RI}\) is the power efficiency metric for the ready idle test;
- \(C_R\) is the raw capacity of the product under test (see subclause 4.2.34);
- \(PA_{RI}(7 200)\) is the average power over the 2 h measurement interval for the ready idle test.

8.4.2 Random Block Access Active Test

For each test phase of the active test, the power efficiency metric represents the rate of data transfer supported per watt of power required by the product under test during a selected stable measurement interval. It is calculated, as shown in Equation 8-2, as the ratio of:

- The operations or throughput rate, during the measurement interval of the active test, expressed in IO/s or MiB/s;
- The average power, during the measurement interval of the active test, measured in watts.

\[
EP_i = \frac{O_i(1 800)}{PA_i(1 800)}
\]

Where:
- \(EP_i\) is the power efficiency metric for Active Test test phase \(i\);
- \(PA_i(1 800)\) is the average power over the 30 min measurement interval for Active Test test phase \(i\);
- \(O_i(1 800)\) is the operations rate over the 30 min measurement interval for Active Test test phase \(i\).

8.4.3 File Access Active Test

For each test phase of the active test, the power efficiency metric represents the rate of data transfer supported per watt of power required by the product under test during a selected stable measurement interval. It is calculated, as shown in Equation 8-3, as the ratio of:

- The throughput rate, during the measurement interval of the active test, measured in MiB/s;
- The average power, during the measurement interval of the active test, measured in watts.
Equation 8-3: Power Efficiency, Active (File Access)

\[ EP_i = \frac{O_i(300)}{PA_i(300)} \]

Where:
- \( EP_i \) is the power efficiency metric for Active Test test phase \( i \);
- \( PA_i(300) \) is the average power over the 5 min measurement interval for Active Test test phase \( i \);
- \( O_i(300) \) is the operations rate over the 5 min measurement interval for Active Test test phase \( i \).

8.4.4 Reporting
The power efficiency metric shall be reported to three significant digits.

8.5 Power Efficiency Metric for RVML Set Removable Media Library Category Systems

8.5.1 Ready Idle Test
For the ready idle test, the power efficiency metric represents the amount of raw capacity supported per watt of power required by the product under test. It is calculated as shown in Equation 8-1, as the ratio of:
- The raw capacity of the product under test, measured in GB;
- The average power, from the ready idle test, measured in watts.

Note: Since tape cartridges themselves do not impact energy consumption, not all tape cartridges that can be present in a given configuration need to be present at the time of the test.

8.5.2 Active Test
For each test phase of the active test, the power efficiency metric represents the rate of data transfer supported per watt of power required by the product under test during a selected stable measurement interval. It is calculated, as shown in Equation 8-2, as the ratio of:
- The operations rate, during the measurement interval of the active test, measured in MiB/s;
- The average power during the measurement interval of the active test, measured in watts.

8.5.3 Reporting
The power efficiency metric shall be reported to three significant digits.

8.6 Power Efficiency Metric for RVML Set Virtual Media Library Category Systems

8.6.1 Ready Idle Test
For the ready idle test, the power efficiency metric represents the amount of raw capacity supported per watt of power consumed by the product under test. It is calculated as shown in Equation 8-1, as the ratio of:
- The raw capacity of the product under test, measured in GB;
- The average power, from the ready idle test, measured in watts.
8.6.2 Active Test

For each test phase of the active test, the power efficiency metric represents the rate of data transfer supported per watt of power required by the product under test during a selected stable measurement interval. It is calculated, as shown in Equation 8-2, as the ratio of:

- The operations rate, during the measurement interval of the active test, reported in MiB/s;
- The average power during the measurement interval of the active test, measured in watts.

8.6.3 Reporting

The power efficiency metrics, when reported, shall be reported to three significant digits.

8.7 Secondary Metrics

8.7.1 Capacity Optimization Metrics

This document defines capacity optimization tests for the Disk Set Online, Disk Set Near-Online, and NVSS Set Disk Access taxonomy categories. The tests result in five binary, secondary metrics, which are given a value of 1 (Yes) if the product under test satisfies the named COM heuristic, and 0 (No) if it does not. The secondary metrics are:

- COMRD based on the delta snapshots heuristic;
- COMWD based on the delta snapshots heuristic;
- COMTP based on the provisioning heuristic;
- COMDD based on the data deduplication heuristic;
- COMC based on the compression heuristic.

This document defines no relationship between the binary, secondary metrics defined in this subclause and the quantitative, primary metrics defined in subclauses 8.2 and 8.3.
9 Disclosure Requirements

9.1 General
This clause lists the information that shall be disclosed in every published test result identified as an SNIA Emerald™ Power Efficiency Measurement test result. Test results identified as an SNIA Emerald™ Power Efficiency Measurement test result shall be generated according to this document.

When units are specified after an item, that that shall be reported in terms of the specified unit.

SNIA Emerald™ Power Efficiency Measurement test results should be reported using the Test Data Report Template [18] provided for this purpose.

9.2 Product Identification
The information identified in this subclause shall be disclosed:
1. Product name;
2. Product model identification.

9.3 Test Metrics

9.3.1 Random Block Access

9.3.1.1 Introduction
For a test of a product in the Disk Set Online, Disk Set Near-Online, and NVSS Set Disk Access taxonomy category using the block access test method, the information identified in this subclause shall be disclosed:

9.3.1.2 Primary Metrics
9.3.1.2.1 Ready Idle Test
1. Average power consumption (W);
2. Raw capacity of product under test (GB);

9.3.1.2.2 Active Tests
9.3.1.2.2.1 Hot Band

9.3.1.2.2.2 Random Read

9.3.1.2.2.3 Random Write

9.3.1.2.2.4 Sequential Read

9.3.1.2.2.5 Sequential Write
1. EP_SW (MiB/s/W).
9.3.1.3 Secondary Metrics (COMs)

9.3.1.3.1 Data Deduplication
1. \( \text{COM}_{\text{DD}} \) - Data deduplication heuristic indicated data deduplication present (Yes or No);
2. Data deduplication present and enabled in product under test during active tests (Yes or No).

9.3.1.3.2 Compression
1. \( \text{COM}_{\text{C}} \) - Compression heuristic indicated compression present (Yes or No);
2. Compression present and enabled in product under test during active tests (Yes or No).

9.3.1.3.3 Thin Provisioning
1. \( \text{COM}_{\text{TP}} \) - Thin provisioning heuristic indicated thin provisioning present (Yes or No);
2. Thin provisioning present and enabled in product under test during active tests (Yes or No).

9.3.1.3.4 Read-Only Delta Snapshots
1. \( \text{COM}_{\text{RD}} \) - Read-only delta snapshot heuristic indicated read-only snapshot present (Yes or No);
2. Read-only delta snapshot present and enabled in product under test during active tests (Yes or No).

9.3.1.3.5 Writable Delta Snapshots
1. \( \text{COM}_{\text{WD}} \) - Writable delta snapshot heuristic indicated writable delta snapshot present (Yes or No);
2. Writable delta snapshot present and enabled in product under test during active tests (Yes or No).

9.3.2 File Access

9.3.2.1 Introduction
For a test of a product in the Disk Set Online, Disk Set Near-Online, and NVSS Set Disk Access taxonomy category using the file access test method, the information identified in this subclause shall be disclosed:

9.3.2.2 Primary Metrics

9.3.2.2.1 Ready Idle Test
1. Average power consumption (W);
2. Raw capacity of product under test (GB);
3. \( \text{EP}_{\text{RI}} \) for Ready Idle (GB/W).

9.3.2.2.2 Active Tests

9.3.2.2.2.1 Video Data Acquisition
1. \( \text{EP}_{\text{VDA}} \) (MiB/s/W).

9.3.2.2.2.2 Database
1. \( \text{EP}_{\text{DB}} \) (MiB/s/W).

9.3.2.2.2.3 Virtual Desktop Integration
1. \( \text{EP}_{\text{VDI}} \) (MiB/s/W).

9.3.2.2.2.4 Software Build
1. \( \text{EP}_{\text{SWB}} \) (MiB/s/W).
9.3.2.3 Secondary Metrics (COMs)

9.3.2.3.1 Data deduplication
1. COMdd - Data deduplication heuristic indicated deduplication present (Yes or No);
2. Data deduplication present and enabled in product under test during active tests (Yes or No).

9.3.2.3.2 Compression
1. COMc - Compression heuristic indicated compression present (Yes or No);
2. Compression present and enabled in product under test during active tests (Yes or No).

9.3.2.3.3 Thin Provisioning
1. COMtp - Thin provisioning heuristic indicated thin provisioning present (Yes or No);
2. Thin provisioning present and enabled in product under test during active tests (Yes or No).

9.3.2.3.4 Read-Only Delta Snapshots
1. COMrd - Read-only delta snapshot heuristic indicated read-only snapshot present (Yes or No);
2. Read-only delta snapshot present and enabled in product under test during active tests (Yes or No).

9.3.2.3.5 Writable Delta Snapshots
1. COMwd - Writable delta snapshot heuristic indicated writable delta snapshot present (Yes or No);
2. Writable delta snapshot present and enabled in product under test during active tests (Yes or No).

9.3.3 RVML Set Removable Media Library and Virtual Media Library Categories

9.3.3.1 Introduction
For a test of a product in the RVML Set Removable Media Library or Virtual Media Library taxonomy category, the information identified in this subclause shall be disclosed:

9.3.3.2 Primary Metrics

9.3.3.2.1 Ready Idle Test
1. Average power consumption (W);
2. Raw capacity of product under test (GB);
3. EPRI for Ready Idle (GB/W).

9.3.3.2.2 Active Tests

9.3.3.2.2.1 Sequential Read
1. EPSR (MiB/s/W).

9.3.3.2.2.2 Sequential Write
1. EPSW (MiB/s/W).

9.4 Test Characterization
The information characterizing the test environment identified in this subclause shall be disclosed:
1. Version of this document according to which testing was performed;
2. Taxonomy set of the product under test;
3. Taxonomy category of the product under test;
4. Taxonomy classification of the product under test;
5. Access method tested (block access or file access);
6. Workload generator name;
7. Workload generator version identifier;
8. Workload script name;
9. Workload script version identifier;
10. For file access tests, identity of the sFlow® agent;
11. For file access tests, sFlow® agent version identifier;
12. For file access tests, identity of the sFlow® collector used;
13. For file access tests, sFlow® collector version identifier;
14. Transport protocol(s) used during testing to access data on product under test.

9.5 Product Under Test Description

9.5.1 Product Under Test Description – General
The information describing the product under test identified in this subclause shall be disclosed:
1. Power input – nominal voltage (V);
2. Power input – nominal frequency (Hz);
3. Power input – number of phases;
4. Average air inlet temperature during test (°C);
5. Is storage protection present and enabled? (Yes or No);
6. Is product under test configured to be no SPOF (Yes or No).
7. Is auto-tiering present and enabled? (Yes or No).

9.5.2 Product Under Test Description – Storage Controllers
The information describing each storage controller component of the product under test identified in this subclause shall be disclosed:
1. Number of controllers of this type;
2. Controller part number;
3. Controller description;
4. Controller main memory size (GiB);
5. Controller volatile cache size (GiB);
6. Controller non-volatile cache size (GiB);
7. Is storage protection present and enabled? (Yes or No).

9.5.3 Product Under Test Description – Power Supplies
The information describing each power supply component of the product under test identified in this subclause shall be disclosed:
1. Number of power supplies of this type;
Disclosure Requirements

2. Power supply part number;
3. Power supply 80 PLUS\textsuperscript{17} rating.

9.5.4 Product Under Test Description – Media Shelves / Drawers
The information describing each media shelf / drawer component of the product under test identified in this subclause shall be disclosed:
1. Number of media shelves / drawers of this type;
2. Media shelf / drawer part number.

9.5.5 Product Under Test Description – Storage Media
The information describing each storage media component (storage device) of the product under test identified in this subclause shall be disclosed:
1. Number of storage media of this type;
2. Storage media vendor name;
3. Media part number;
4. Media type;
5. Media form factor;
6. Raw capacity of the storage media (GB);
7. Media rotational speed (not applicable to NVSS Set or RVML Set Removable Media Library Category products);
8. Media volatile cache size (MiB);
9. Media non-volatile cache size (MiB);
10. Media interface type;
11. Media interface speed (Mb/s);
12. Does media contribute to formatted capacity? (Yes or No).

9.5.6 Product Under Test Description – Removable Storage Media
The information describing each removable storage media component (storage device) of the product under test identified in this subclause shall be disclosed:
1. Number of removable storage media drive slots in product under test;
2. Number of drives for removable storage media;
3. Number of robotics units for removable storage media;
4. Number of removable media cartridge slots in product under test;
5. Number of removable media cartridges present in product under test;
6. Removable media cartridge type(s).

9.5.7 Product Under Test Description – Host Protocol Controllers
The information describing each host protocol controller component of the product under test identified in this subclause shall be disclosed:
1. Number of host protocol controllers of this type;
2. Host protocol controller part number;
3. Host protocol(s) supported;
4. Host protocol controller nominal data rate (Gb/s).
Annex A (Normative) Suggested Power and Environmental Meters

A.1 Overview

The power and temperature meters that should be used are those approved for use with the SPEC Power® benchmark\[19\] and appearing in the SPEC PTDaemon™ Tool\[20\] on the List of Accepted Power Analyzers and List of Accepted Temperature Sensors.

For more information on the appropriate use of a power meter, see the User Guide for the SNIA Emerald™ Power Efficiency Measurement Specification\[14\].

A.2 Alternate Meter Usage

A test sponsor may perform a SNIA Emerald™ Power Efficiency Measurement using a meter not on the list (“alternate meter”). If a measurement uses an alternate meter, sufficient documentation about the meter and its configuration and calibration to ensure that its use provides measurement data equivalent to that provided by the recommended meters shall be disclosed.

Test sponsors using an alternate meter shall attest to its equivalence to the meters on the recommended list at the time of the test in the following areas:

- Accuracy;
- Resolution;
- Calibration.

---

4 SPEC Power® is the trademark of a product supplied by the Standard Performance Evaluation Corporation. This information is given for the convenience of users of this document and does not constitute an endorsement by the SNIA of the product named.
Annex B (Normative) Measurement Requirements

B.1 Random Block Access Data Collection and Processing Requirements

Table B-3  File Access Summary
Annex C (Normative) Stable Storage

Stable storage is storage that retains data, for a minimum of 72 h without external power, in the case of:

1. Repeated power failures, including cascading power failures;
2. Hardware failures (of any board, power supply, etc.);
2. Repeated system crashes, including reboot cycle.

This definition does not address failure of the storage itself. For example, failures of disks or nonvolatile RAM modules are not addressed in the definition of stable storage.

We further clarify the definition of the term "stable storage" to resolve any potential ambiguity. This clarification is necessary since the definition of stable storage has been, and continues to be, a point of contention. Therefore, for the purposes of this document, stable storage is defined in terms of the following operational description:

To offer stable storage, the product under test shall be able to tolerate without loss of committed data:

1. Power failures of the product under test's primary power source, including cascading power failures, with a total duration of no longer than 72 h;
2. Non-destructive transient failures (temporary failure which does not require replacement or upgrade of the failed hardware or software component) of any hardware or software component in the product under test which result in a system crash. Multiple and/or cascading failures are excluded;
3. Manual reset of the entire product under test, or of any of its components involved in providing services, if required to recover from transient failures.

If the product under test allows data to be cached in intermediate storage, after a response to the client indicating that the data has been committed, but before the data is flushed to permanent storage, then there shall be a mechanism to ensure that the cached data survives failures of the types defined above.

Committed data may or may not be preserved in the face of unbounded numbers of cascading hardware or software errors that combine to prevent the system from performing any significantly useful work.
Annex D (Normative) Vdbench

**Annex D (Normative) Vdbench**

Vdbench is an IO performance test tool developed by Oracle Corporation. The Vdbench software specified on the *Download Material for SNIA Emerald™ Testing*[^13] web page for use with this document shall be used for block access testing. The web page also provides access to the Vdbench software and related materials.

[^13]: Refer to the original document for the specific web page reference.
Annex E (Normative) Vdbench Test Scripts

The Vdbench test tool is directed by a test script that parameterizes a run of Vdbench. Two Vdbench Test Scripts are provided for block access testing. Scripts are provided for:

- Block access testing of Online and Near-Online category devices;
- Block access testing of Removable Media Library and Virtual Media Library category devices.

The Vdbench Test Scripts provided on the Download Material for SNIA Emerald™ Testing[13] web page for use with this document shall be used for block access testing.
Annex F (Normative) SPEC SFS® 2014 Benchmark

SPEC SFS® 2014 is a performance benchmark developed by the Standard Performance Evaluation Corporation (SPEC). This document describes the use of SPEC SFS® 2014 Benchmark as the workload generator for file access testing.

The SPEC SFS® 2014 software specified on the Download Material for SNIA Emerald™ Testing web page for use with this document shall be used for file access testing. The web page also provides access to the SPEC SFS® 2014 software and related materials.

SPEC SFS® 2014 benchmarking software is orderable for a fee from the SPEC website Purchase Current SPEC Benchmark Suites.
Annex G (Normative) File Access IO Load Driver Configuration File

The SPEC SFS® 2014 benchmark tool is directed by configuration file that parameterizes a run of the SPEC SFS® 2014 benchmark.

The File Access IO Load Driver Configuration File provided on the Download Material for SNIA Emerald™ Testing web page for use with this document shall be used for file access testing.
Annex H (Informative) sFlow®

Annex H (Informative) sFlow®

sFlow® is an industry standard for sampling packet traffic and interface counter statistics of devices participating in high speed networks. The sFlow® protocol is maintained by sFlow.org[9].

An sFlow® Agent is software that runs within a network device, combining data into sFlow® datagrams that are sent across the network to an sFlow® Collector. The sFlow® Agent is typically implemented by the network equipment vendor as a software feature.

An sFlow® Collector is software that accepts sFlow® datagrams and performs processing and analysis on the received data, producing reports for the user. There are multiple sFlow® Collectors available commercially.

A list of network equipment that supports sFlow® and a list of available sFlow® Collectors are available from sFlow.org[9].
Annex I (Normative) COM Test Data Set Generator

The COM Test Data Set Generator[^16] is open-source software that creates data sets used in performing SNIA Emerald™ Power Efficiency Measurements.

The COM Test Data Set Generator software specified on the Download Material for SNIA Emerald™ Testing[^13] web page for use with this document shall be used COM testing.

[^16]: Reference to the COM Test Data Set Generator version.
[^13]: Reference to the SNIA Emerald™ Testing Download Material location.
Annex J (Informative) gzip

Annex J  (Informative) gzip

Gzip\(^{[15]}\) is an open-source file compression utility.
