- ◆ NFS, pNFS and FedFS: A Modern Datacenter Network Protocol
 - ◆ The NFSv4 protocol undergoes a repeated lifecycle of definition and implementation. This presentation will be based on years of experience implementing server-side NFS solutions up to NFSv4.1.
 - ◆ Practical examples of how to implement NFSv4.1 and pNFS are fragmentary and incomplete. This presentation will take a step-by-step guide to implementation.

NFS; Ubiquitous & Everywhere

- ◆ NFS is ubiquitous and everywhere
- ◆ NFSv3 very successful
 - ◆ Protocol adoption is over time, and there have been no big incentives to change
- ◆ Industry – and hence NFS – doesn't stand still
 - ◆ NFSv2 in 1983
 - ◆ NFSv3 in 1995
 - ◆ NFSv4 in 2003, updated 2015
 - ◆ NFSv4.1 in 2010
 - ◆ NFSv4.2 to be agreed at IETF shortly
 - ◆ Faster pace for minor revisions
 - ◆ <http://datatracker.ietf.org/wg/nfsv4>
- ◆ NFSv3 very successful
 - ◆ Protocol adoption is over time, and there have been no big incentives to change

Evolving Requirements

- ◆ Adoption was historically slow; why?
 - ◆ Lack of clients was a problem with NFSv4
 - ◆ NFSv3 was just “good enough”
- ◆ That’s changed & pace of adoption now increasing
- ◆ Industry is changing, as are requirements
 - ◆ Economic Trends
 - › Cheap and fast computing clusters
 - › Cheap and fast network (1GbE to 10GbE, 40GbE and 100GbE in the datacenter)
 - › Cost effective & performant storage based on flash, flash & SATA
 - ◆ Performance
 - › Exposes NFSv3 single threaded bottlenecks in applications
 - › Increased demands of compute parallelism and consequent data parallelism
 - › Analysis begets more data, at exponential rates
 - › Competitive edge (ops/sec)
 - ◆ Business requirement to reduce solution times
 - › Beyond performance; NFSv4.1 brings increased scale & flexibility
 - › Outside of the datacenter; requires good security, scalability
 - › Now VMware and other application support

NFSv4 and beyond

- Areas addressed by NFSv4, NFSv4.1 and pNFS
 - ◆ Security
 - ◆ Uniform namespaces
 - ◆ Statefulness & Sessions
 - ◆ Compound operations
 - ◆ Caching; Directory & File Delegations
 - ◆ Parallelization; Layouts & pNFS
- New features in NFSv4.2
- FedFS (in addendum slides)
 - ◆ FedFS: Global namespace; IESG has approved Dec 2012

➤ We'll cover

- ◆ Selecting the application for NFSv4.1
- ◆ Planning;
 - › Filenames and namespace considerations
 - › Firewalls
 - › Understanding statefulness
 - › Security
- ◆ Server & Client Availability
- ◆ Where Next
 - › Considering pNFS

➤ This is a high level overview

- ◆ Use SNIA white papers and vendors (both client & server) to help you implement

Selecting the Parts

- 1 – An NFSv4.1 compliant server
 - ◆ Question: files, blocks or objects?
- 2 – An NFSv4.1 compliant client
 - ◆ Will almost certainly be Linux based; no native NFS4 Windows client
 - ◆ Some applications are their own clients; Oracle, VMware etc
 - ◆ See Linux client discussion later
- 3 – Auxiliary tools;
 - ◆ Kerberos, DNS, NTP, LDAP
- 4 – If you can, use NFSv4.1 in preference to NFSv4.0

Selecting an Application

➤ First task; select an application or storage infrastructure for NFSv4.1 use

- ◆ Home directories
- ◆ HPC applications
- ◆ VMware & other virtualization tools

➤ Don't choose or migrate...

- ◆ Oracle based applications: use dNFS built in to the Oracle kernel
- ◆ “Oddball” applications that expect to be able to internally manage NFSv3 “maps” with multiple mount points, or auxiliary protocols like mountd, statd etc;
- ◆ Any application that requires UDP; NFSv4 doesn't support it

NFSv4 Stateful Clients

- NFSv4 gives client independence
 - ◆ Previous model had “dumb” stateless client; server had the smarts
- Allows delegations & caching
- No automounter required, simplified locking
 - ◆ Mounting & locking incorporated into the protocol
 - ◆ Simplifies administration
- Why?
 - ◆ Compute nodes work best with local data
 - ◆ NFSv4 eliminates the need for local storage
 - ◆ Exposes more of the backend storage functionality
 - › Client can help make server smarter by providing hints
 - ◆ Removes major source of NFSv3 irritation; stale locks

NFSv4.1 Delegations

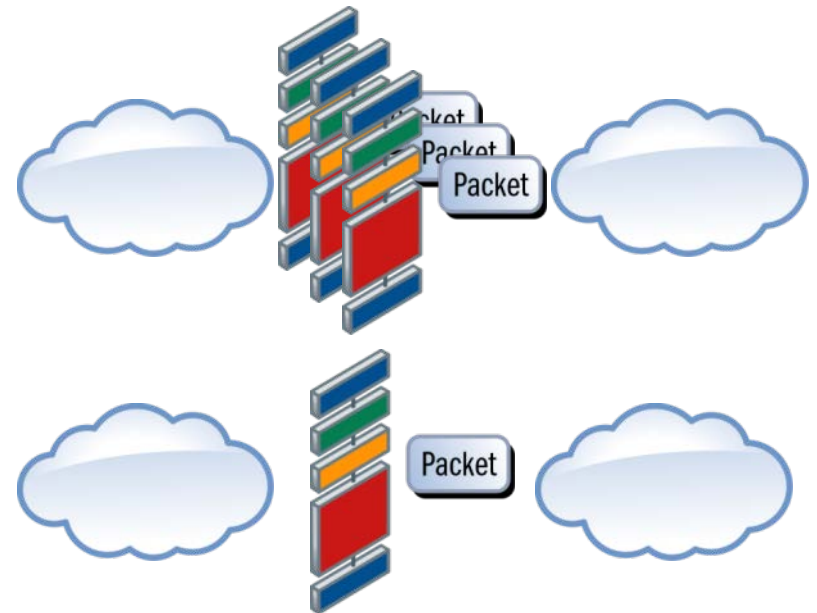

- Delegations optional
 - ◆ Only when sharing allows & server grants
- Server delegates certain responsibilities to the client
 - ◆ Directory & file
- At OPEN, the server can provide
 - ◆ READ delegation: server guarantees no writers
 - ◆ WRITE delegation: server guarantees exclusive access
- Allows client to locally service operations
 - ◆ E.g OPEN, CLOSE, LOCK, LOCKU, READ, WRITE

NFSv4.1 Sessions

- NFSv3 server never knows if client got reply message
- NFSv4.1 introduces Sessions
 - ◆ Major protocol infrastructure change
 - ◆ Exactly Once Semantics (EOS)
 - ◆ Bounded size of reply cache
 - ◆ Fixes issues with NFSv4.0 callbacks thru firewalls
- A session maintains the server's state relative to the connections belonging to a client
- Action
 - ◆ None, delegation & caching transparently provided by client & server
 - ◆ NFSv4.1 advantages include session lock clean up automatically

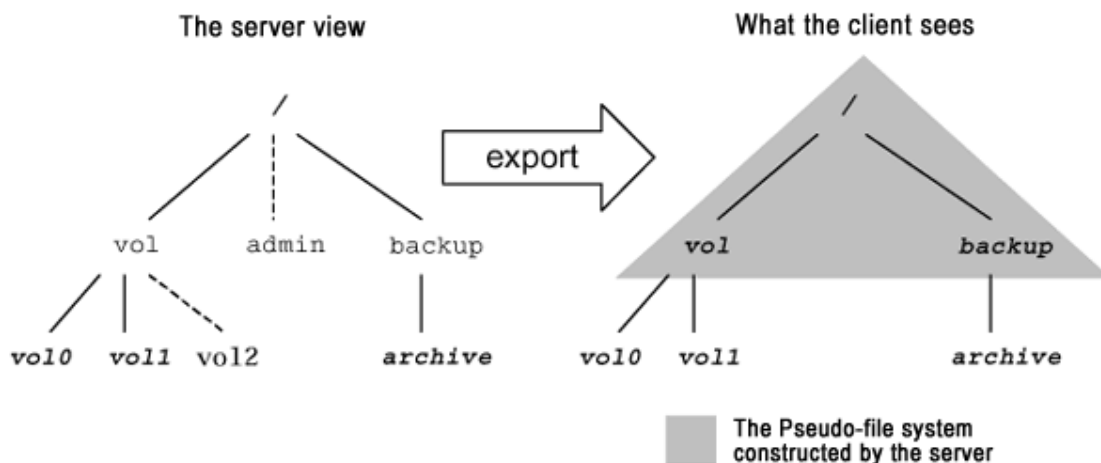

NFSv4 Compound Operations

- NFSv3 protocol can be “chatty”; unsuitable for WANs with poor latency
- Typical NFSv3; find, open, read & close a file
 - ◆ Several synchronous operations over the wire
- NFSv4 compounds into a single operation
 - ◆ LOOKUP, GETATTR, OPEN, READ, SETATTR, CLOSE
 - ◆ Reduce wire time
 - ◆ Simple error recovery

NFSv4 Namespace

- Uniform and “infinite” namespace
 - ◆ Moving from user/home directories to datacenter & corporate use
 - ◆ Meets demands for “large scale” protocol
 - ◆ Unicode support for UTF-8 codepoints
- No automounter required
 - ◆ Simplifies administration
- No application changes
 - ◆ Access files by well-known paths as usual

NFSv4 Namespace

➤ Namespace Example

- ◆ Server exports
 - > /vol/vol0
 - > /vol/vol1
 - > /backup/archive

➤ Mount root / over NFSv3:

- ◆ Allows the client to list the contents of vol/vol2

➤ Mount root / over NFSv4:

- ◆ If /vol/vol2 has not been exported and the pseudo filesystem does not contain it; the directory is not visible
- ◆ An explicit mount of vol/vol2 will be required.

➤ Namespaces

➤ Action

- ◆ Consider using the flexibility of pseudo-filesystems to permit easier migration from NFSv3 directory structures to NFSv4, without being overly concerned as to the server directory hierarchy and layout.

➤ However;

- ◆ If there are applications that traverse the filesystem structure or assume the entire filesystem is visible, caution should be exercised before moving to NFSv4 to understand the impact presenting a pseudo filesystem
- ◆ Especially when converting NFSv3 mounts of / (root) to NFSv4

NFSv4 I18N Directory & File Names

➤ Directory and File Names

- ◆ NFSv4 uses UTF-8
 - Backward compatible with 7 bit ASCII
- ◆ Check filenames for compatibility
 - NFSv3 file created with the name René contains an 8 bit ASCII
 - UTF-8 é indicates a multibyte UTF-8 encoding, which will lead to unexpected results

➤ Action

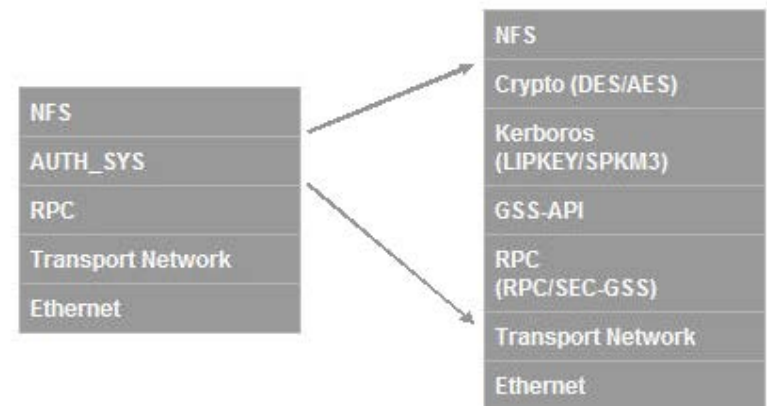

- ◆ Review existing NFSv3 names to ensure that they are 7 bit ASCII clean

- ◆ These aren't;

ı ç £ ¤ ¥ ¦ § ¨ © º « ¬ ® ¯
° ± ² ³ ´ µ ¶ · ¸ ¹ º » ¼ ½ ¾ ¿
À Á Â Ã Ä Å Æ Ç È É Ê Ë Ì Í Î Ï
Ð Ñ Ò Ó Ô Õ Ö × Ø Ù Ú Û Ü Ý Þ ß
à á â ã ä å æ ç è é ê ë ì í î ï
ð ñ ò ó ô õ ö ÷ ø ù ú û ü ý þ ÿ

NFSv4 Security

- Strong authentication framework
- Access control (ACLs & ACEs) for security
- Security with Kerberos
 - ◆ Negotiated RPC security that depends on cryptography, RPCSEC_GSS
- NFSv4 can be implemented without implementing Kerberos security
 - ◆ Not advised; but it is possible

- Implementing without Kerberos
 - ◆ AUTH_SYS (as in NFSv3) authentication is a last resort!
- NFSv3 represents users and groups via 32 bit integers
 - ◆ UIDs and GIDs with GETATTR and SETATTR
- NFSv4 represents users and groups as strings
 - ◆ user@domain or group@domain
- Requires NFSv3 UID and GID 32 bit integers be converted to all numeric strings
 - ◆ Client side;
 - > Run idmapd6
 - > /etc/idmapd.conf points to a default domain and specifies translation service nsswitch.
 - ◆ Incorrect or incomplete configuration, UID and GID will display nobody
 - ◆ Using integers to represent users and groups requires that every client and server that might connect to each other agree on user and group assignments

NFSv4 Security

- Implementing with Kerberos
- Find a security expert
 - ◆ Requires to be correctly implemented
 - ◆ Do not use NFSv4 as a testbed to shake out Kerberos issues!
- User communities divided into realms
 - ◆ Realm has an administrator responsible for maintaining a database of users
 - ◆ Correct user@domain or group@domain string is required
 - ◆ NFSv3 32 bit integer UIDs and GIDs are explicitly denied access
- NFSv3 and NFSv4 security models are not compatible with each other
 - ◆ Although storage systems may support both NFSv3 and NFSv4 clients, be aware that there may be compatibility issues with ACLs. For example, they may be enforced but not visible to the NFSv3 client.
- Resources:
 - ◆ <http://web.mit.edu/kerberos/>

➤ Action

- ◆ Review security requirements on NFSv4 filesystems
- ◆ Use Kerberos for robust security, especially across WANs
- ◆ If using Kerberos, ensure it is installed and operating correctly
 - Don't use NFSv4 as a testbed to shake out Kerberos issues

➤ Consider using Windows AD Server

- ◆ Easy to manage environment, compatible

➤ Last resort

- ◆ If using NFSv3 security, ensure UID and GUID mapping and translation is uniformly implemented across the enterprise

➤ Firewalls

- ◆ NFSv3 promiscuously uses ports beyond static 111 and 2049; including 1039, 1047, 1048 (and possibly others...)
- ◆ NFSv4 has no “auxiliary” protocols like portmapper, statd, lockd or mountd
 - › Functionality built in to the protocol
 - › Uses port 2049 with TCP only
- ◆ No floating ports required & easily supported by NAT

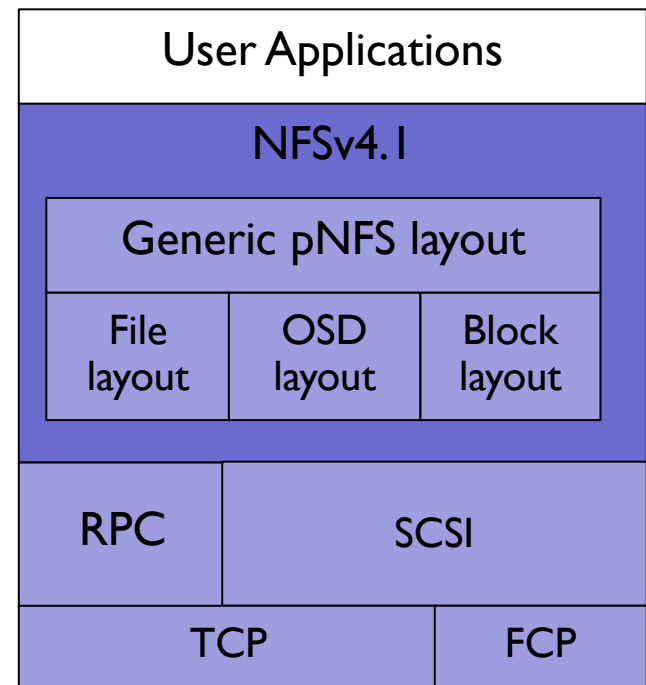

➤ Action

- ◆ Simplified and stronger firewall management over single port 2049 for TCP
- ◆ NFSv4.0 callback issues with firewalls; use NFSv4.1

Relationship of pNFS to NFSv4.1

- RFC 7530 – Network File System (NFS) Version 4 Protocol
 - ◆ NFSv4 (updated from RFC 3530 based on experience)
- RFC 5661 – Network File System (NFS) Version 4 Minor Version 1 Protocol
 - ◆ Specifies Sessions, Directory Delegations, and parallel NFS (pNFS) for files
- RFC 5663 - Parallel NFS (pNFS) Block/Volume Layout
- RFC 5664 - Object-Based Parallel NFS (pNFS) Operations
- pNFS is dependent on session support, which is only available in NFSv4.1

OSD: Object based Storage Device

➤ NFSv4.1 (pNFS) can aggregate bandwidth

- ◆ Modern approach; relieves issues associated with point-to-point connections

□ pNFS Client

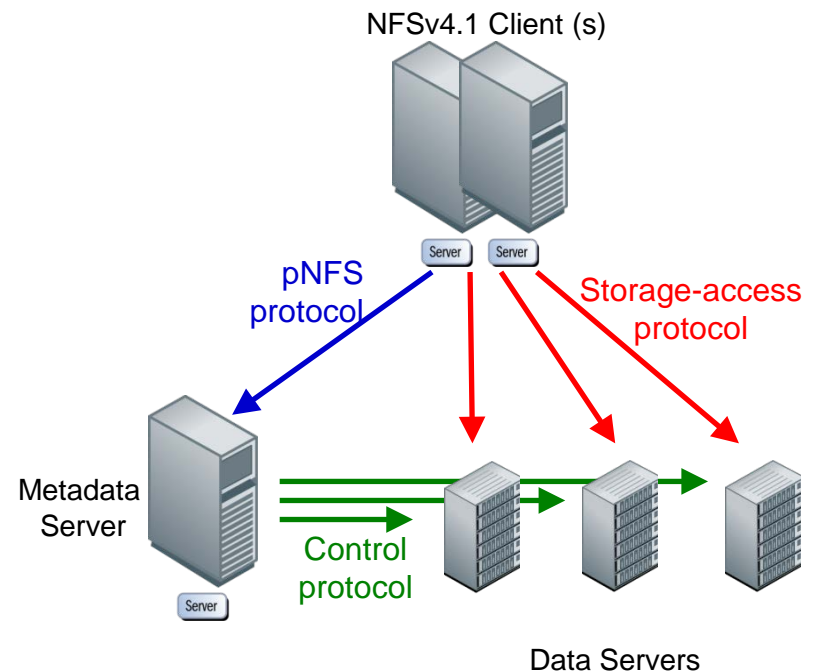

- Client read/write a file
- Server grants permission
- File layout (stripe map) is given to the client
- Client parallel R/W directly to data servers

□ Removes IO Bottlenecks

- No single storage node is a bottleneck
- Improves large file performance

□ Improves Management

- Data and clients are load balanced
- Single Namespace

Layouts

- ◆ Files, objects and block layouts
- ◆ Provides flexibility for storage that underpins it
- ◆ Location transparent
 - › Striping and clustering

Examples

- ◆ Blocks, Object and Files layouts all available from various vendors

pNFS Filesystem Implications

- Files, blocks, objects can co-exist in the same storage network
 - ◆ Can access the same filesystem; even the same file
- NFS flexible enough to support unlimited number of storage layout types
 - ◆ Three IETF standards, files, blocks, objects
 - ◆ Others evaluated experimentally
- NAS vs SAN; no-one cares any more
 - ◆ IETF process defines how you get to storage, not what your storage looks like
 - ◆ NetApp pNFS implemented differently from Linux or Panasas or EMC or...

pNFS Terminology

◆ Metadata Server; the MDS

- ◆ Maintains information about location and layout of files, objects or block data on data servers
- ◆ Shown as a separate entity, but commonly implemented on one or across more than one data server as part of an array

◆ pNFS protocol

- ◆ Extended protocol over NFSv4.1
- ◆ Client to MDS communication

◆ Storage access protocol

- ◆ Files; NFS operations
- ◆ Objects: OSD SCSI objects protocol (OSD2)
- ◆ Blocks; SCSI blocks (iSCSI, FCP)

◆ Control protocol

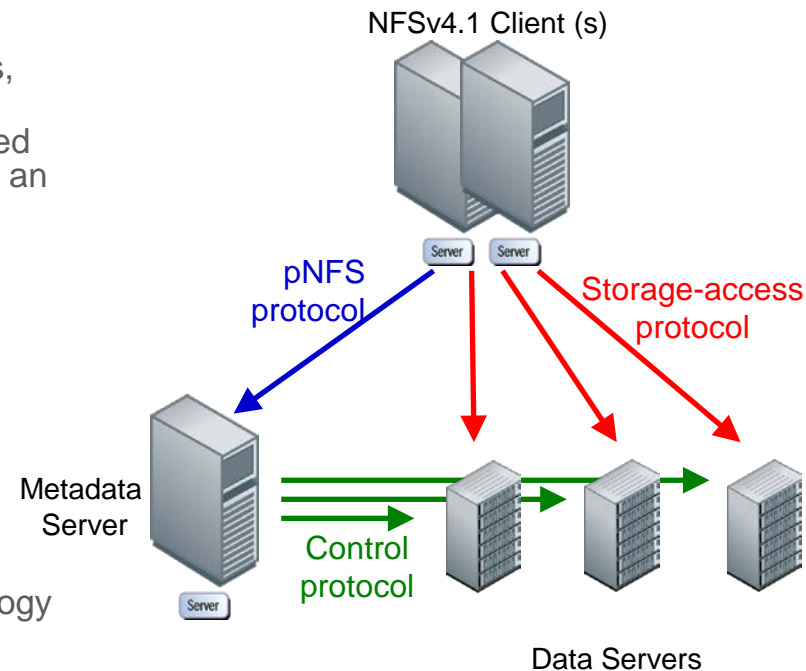

- ◆ Not standardised; each vendor uses their own technology to do this

◆ Layout

- ◆ Description of devices and sector maps for the data stored on the data servers
- ◆ 3 types; files, block and object

◆ Callback

- ◆ Asynchronous RPC calls used to control the behavior of the client during pNFS operations

- ◆ Client requests layout from MDS
 - ◆ Layout maps the file/object/block to data server addresses and locations
 - ◆ Client uses layout to perform direct I/O to the storage layer
 - ◆ MDS or data server can recall the layout at any time using callbacks
 - ◆ Client commits changes and releases the layout when complete
 - ◆ pNFS is optional
 - ◆ Client can fall back to NFSv4
- ◆ pNFS operations
 - ◆ LAYOUTCOMMIT Servers commit the layout and update the meta-data maps
 - ◆ LAYOUTRETURN Returns the layout or the new layout, if the data is modified
 - ◆ GETDEVICEINFO Client gets updated information on a data server in the storage cluster
 - ◆ GETDEVICELIST Clients requests the list of all data servers participating in the storage cluster
 - ◆ CB_LAYOUT Server recalls the data layout from a client if conflicts are detected

pNFS Pre-requisites

- ◆ NFSv4.1 and pNFS capable server
 - ◆ Contact your NAS vendor for availability
 - ◆ Commercial products available for all of files, blocks and object types
 - ◆ Open source Linux pNFS server available
 - › See <http://linux-nfs.org>
- ◆ pNFS capable client
 - ◆ Only Linux to date

Meta-data node provides the pNFS client with the IP information for the DS. In this example – 172.17.40.173

Information is cached for life of the layout or until recalled (for example, when the data is moved)

Federated File System: FedFS

➤ Federated File System

- ◆ Uniform namespace that has local and geographically global referral infrastructure
- ◆ Accessible to unmodified NFSv4 clients
- ◆ Addresses directories, referrals, nesting, and namespace relationships

➤ Client finds namespace via DNS lookup

- ◆ Sees junctions (directories) and follows them as NFSv4 referrals

What is FedFS?

- FedFS is a set of open protocols that permit the construction of a scalable, cross-platform federated file system namespace accessible to unmodified NFSv4 clients.
- Key points:
 - ◆ Unmodified clients
 - ◆ Open: cross-platform, multi-vendor
 - ◆ Federated: participants retain control of their systems
 - ◆ Scalable: supports large namespaces with many clients and servers in different geographies

FedFS Protocols

Namespace Management

- 1 NSDB Management (LDAP)
- 2 Junction Management (ONC RPC)

Namespace Navigation

- 3 Namespace discovery (DNS)
- 4 Junction resolution (LDAP)

FedFS Example

The illusion:

- The user and application software see a simple, hierarchical namespace

The reality:

London

Frankfurt

Paris

- Behind the scenes, simple management operations allow data mobility for high performance, high reliability, and high availability

FedFS Example

The user requests

`/home/alice`:

1. The client attempts to access `/home/alice` on server **foo**.
2. Server **foo** discovers that `home` is a namespace junction and determines its location using the FedFS NSDB service.
3. Server **foo** returns an NFSv4 referral to the client directing it to server **bar's** `/users`.
4. The client accesses `/users/alice` on server **bar**.

Benefits of FedFS

- ❖ Simplified management
 - ◆ Eliminates complicated software such as the automounter
- ❖ Separates logical and physical data location
 - ◆ Allows data movement for cost/performance tiering, worker mobility, and application mobility
- ❖ Enhances:
 - ◆ Data Replication
 - › Load balancing or high availability
 - ◆ Data Migration
 - › Moving data closer to compute or decommissioning systems
 - ◆ Cloud Storage
 - › Dynamic data center, enterprise clouds, or private internet clouds.
